However, we need to remember that the Web as hypermedia or hypertext, is itself only a delivery medium for information or knowledge. Hypertext does not possess a single or normative information structure—hypertext documents are created to conform or fit to a structure, imposed by their authors. At one extreme this structure might be highly ordered, supported by a constrained and sequential set of links; whilst at another extreme, the hypertext may be nonsequential and supported only by referential links. In many cases, a coherent hypertext document, such as a Web site, might comprise a mix of these structures. It is, then, the nature and application of these structures that determines the effectiveness of engagement with knowledge carried in the Web. Furthermore, to maximise engagement, the knowledge needs to conform to a structure that best fits or suits both the type of knowledge being conveyed, and the objectives set by the author for the types of interactions a user should have with it. As Jonassen points out:

> *Few designers of hypertext believe that hypertext knowledge bases should be unstructured and totally nonsequential so that users would have no guidance about the information they access. Even Nelson (1981) concedes that totally nonsequential hypertext can be disorderly and could lead to "idiosyncratic and exceptional forms of connections". Nonsequential hypertext also results in navigation problems (getting lost in hyperspace), as well as integration and synthesis problems. (Jonassen, 1990 85)*

This is the context, then, in which any Web site needs to be designed. Concern has to be taken to represent the various knowledge types in appropriate structures and to build into these structures sufficient scope for the desired learner–material interactions.

Designing For Learning

There are a range of theories available to us in designing the structures for a range of knowledge types and learner–material interactions, all based in an understanding of how people learn and each offering only a partial explanation of learning. Undoubtedly, the most prevalent set of theories in this context, in terms of their application, are cognitivist based and collectively encompass views on information processing; that is, they are largely related to views about how learners perceive, process, store and recall information. As a basis for designing learning environments, or more typically, learning activities, these theories appear adequate and well-grounded. However, they also tend to produce prescriptive and inflexible conditions or principles for learning and further, they are premised on fundamental assumptions about the nature of knowledge. Of late, these assumptions are being increasingly questioned and as a result, theories of learning and instruction that are closely referenced to these assumptions have been found wanting.

There are a number of theoretical stances that currently serve as a basis for both critiquing purely cognitivist approaches to instructional design, and for guiding the development of alternative designs. These include theories of situated cognition, cognitive apprenticeship, constructivism and the social development of knowledge. It should be made clear that such theories are not necessarily in conflict with cognitivist views of learning but that they perhaps extend or adapt cognitivist models. However, in the cases of both constructivism and conversational views of learning, there are held to be essential and fundamental differences with purely cognitive approaches. It is in constructivist and conversational theories that the design for *Learning with software: Pedagogy and practices* has its conceptual framework.

The Web In A Conversational Framework

Learning environments designed in line with a conversational framework must include discursive, adaptive, interactive and reflective components (Laurillard, 1993 100). That is, for each of these components, the learner (or reader, as we might call them in the case of a Web site) must not only have access to the major conceptions being explained or advanced but also be able to act on these explanations, to obtain feedback on their own conceptions of the same or different information, and be able to adapt the Web materials as a result of reflection. This is all completed in a framework of dialogue.

Obviously, in the case of providing information for learning on the Web, there can be no synchronous dialogue; yet there does exist the possibility for developing asynchronous dialogue—between the students and the originator of the Web materials, and also between readers. There further exists scope for adapting the information on the Web site by adding to it. Thus, in the sense of creating a conversational framework, particularly as it is interpreted and applied by Laurillard(Laurillard, 1993; Laurillard, 1995), Pask (Pask, 1976), Ramsden (Ramsden, 1992), and particularly by Vygotsky (Vygotsky, 1962), where dialogue is seen as a mediation between the known and the unknown or between the learner (reader) and the object of learning, the Web does provide a workable vehicle, especially in the application of asynchronous forums. However, it is not, perhaps, the ideal vehicle—at best it facilitates parts of the conversational framework described above, or perhaps stimulates some of the elements of instructional dialogue, even if those elements (such as the taking of action on the information) occur in the learner's (reader's) head. Moreover, the provision of intrinsic and meaningful feedback using the Web is especially problematic—in this sense the Web is not truly interactive and has no specific goal outside the goal constructions imposed by the learner.

Structures And Knowledge Acquisition

Building knowledge structures in hypertext, as with the Web, is a matter of representing interconnected segments of information, where the interconnections are usually associative and perhaps part of a complex semantic network. Essentially the links in a hypertext information base are used to imply a relationship between two or more pieces of information, as well as to make explicit a pathway between them (Horney, 1993). Yet unlike a coherent and linearly constructed argument of the type that characterises knowledge represented in a paper-based medium, the associations of information found on a Web site, no matter how complex they are, cannot by themselves represent knowledge simply by implying a relationship between two or more items of information—associating items of information does not equate to the construction of knowledge. For knowledge to be constructed, the reader has to make sense of the information association, by understanding the meaning of the association.

Thus where the Web is used to represent complex knowledge types, such as academic knowledge, it is important to make the associations or links between items or networks of information explicit. Moreover, to embed the use of the Web in a conversational framework, it is necessary to emphasise dialogue between the learner (reader) and the object of learning (the material on the Web), and to provide the facilities for this to occur.

Designing For Learning On The Web

In light of both conversation frameworks and constructivist theory, learning environments on the Web require certain pedagogical characteristics, including facilities for:

- dialogue, between:
    —learner and materials (information);
    —learner and content author (instructor);
- learners to take action on information;
- learners to negotiate task goals;
- learners to reflect and interact with descriptions of the world;
- extending or adapting the materials (information);
- providing feedback, especially intrinsic feedback, on learners' actions.

One solution to the provision of all these characteristics is in the use of forum software, software that enables asynchronous dialogue between, learner or reader and other learners; learner and information; and learner and content author. It also facilitates the taking of action on information and, if its use is structured accordingly (that is, if the task goals are described in an appropriate activity), provides a means more generally for the articulation and negotiation of knowledge. Moreover, since it promotes asynchronous dialogue, it infers that learners will be led to reflect on content before offering their own view of the world in the form of a description, or on modifying someone else's (i.e. a fellow learner's, or instructor's) descriptive view of the world. In this sense, the key to the proper use of forums lies with the setting and negotiating of task goals.

Predicting Engagement

Providing multiple access points to information on the Web and providing different ways of navigating information in this medium, is potentially an exciting way of making content material relevant and accessible to a range of readers. However, conceptually this approach presents problems. Not only is it unlikely that the designer of a Web site will be able to represent or provide scope for the navigational preferences of all readers, it is also impossible to predict how a reader will engage and interact with information represented on the Web. Indeed, there is some anecdotal evidence in the author's studies of tertiary students using the Web for learning in pre–service teacher education, that information is processed more superficially (i.e. scanning information or randomly accessing information in short snippets, with no sense of coherence or meaning for the content being engaged) than it would be if carried in a traditional medium, such as a book based in linear constructions. Indeed, this evidence is reinforced in similar observations made by others (Burbules & Callister, 1996).

As a means of professional development in teacher education (which is a focus for the Web site, *Learning with software: Pedagogy and practices)*, there might be a tendency to see the Web as a convenient, valuable and inexpensive medium. Certainly it can provide the means and resources for professionals to think about their own and others' practices, to question their own assumptions in a given domain—but it cannot presuppose that readers will actively process given information in these ways. At best, it can be hoped that readers will reflect on their own experiences or perhaps use the material presented to construct or guide their professional experiences in some way. But effective professional development, as with all learning, has to provide active means of processing and communicating experiential, empirical and theoretical knowledge—and it is unclear that the Web can comprehensively provide these means.

Narrative

Narrative is both a necessary and desirable way of representing some knowledge types, particularly experiential knowledge, which can be best provided for by using a range of conventions deriving from narrative and storytelling as text genres. Furthermore, almost all readers or Web users, can be expected to have a well–developed sense of narrative, since they will have been repeatedly exposed to this genre in both formal and informal learning environments. Indeed, the role of narrative in the representation of knowledge is central to our cognition from earliest childhood (Plowman, 1996, 96).

In this context, the Web is problematic. The key features of narrative are linearity, temporality and causality (Plowman, 1996), whilst the Web is a medium that is non–linear, non–temporal and offers no explicit representations of causality. Thus, in terms of it features as a hypermedia or hypertext information base, the Web is likely to interrupt or disrupt the construction of knowledge on the part of the learner or reader, when the reader is engaging narrative in this medium. Not only can the hyperlinks built into narrative text represented on the Web, disrupt the process of constructing meaning in the text, but also the reader's interaction with the computer (necessary in order to effect a decision or choice) is likely to interfere with the same cognitive process. Moreover, whilst the Web invites or necessitates narrative, or indeed, any text, to be broken down and represented in discrete units, this fact will undoubtedly disrupt the flow of the text in its reading, and thus interfere with the reader's attempts to make meaning.

The solution to this problem is not simplistic, but involves the design of structures which support the reader or learner in generating meaning and knowledge from narrative texts on the Web. This can be done by keeping the fracturing of narrative texts to a minimum and ensuring that operational and navigational user–computer interactions are simple. Thus, in narrative texts designers need to:

- keep hyperlinks to a minimum;
- avoid breaking texts down into discrete elements that disrupt the construction of meaning;
- employ media elements that can enhance or help represent narrative (i.e. auditory forms);
- avoid embedding interactive tasks (i.e. tasks that engage the learner in making complex decisions or navigational choices) into narrative texts.

Moreover, it is also important to consider building into narrative knowledge structures in hypertext, associations or nodes of information that are differential or, in the words of Burbules and Callister (1996), 'privileged', to avoid every association of information appearing arbitrary—so, for example, to privilege the idea of a temporal sequence or of a storyline, so as to provide the user or reader with a starting point, a centre and an exit:

> Problematizing given narratives is one thing; proposing alternative readings is another; but the very constructivist theory that encourages these also explains why a reading with no centre is no reading at all. (Burbules & Callister, 1996 33)

Conclusion

In this paper, I have raised a number of issues centred on the use of the Web as a medium for carrying various knowledge types; and particularly, issues that might mitigate against the use of the Web as a ubiquitous and generic instructional medium. Designers of Web sites need to be mindful of the limitations of this medium as a resource for learning, but also be aware of the possibilities offered in design approaches guided by conversational and constructivist frameworks. More particularly, it is important for Web designers to consider how to best represent knowledge in all its forms, especially knowledge that is derived from text genres, such as narrative, that are not readily or easily adaptable to hypermedia.

Connecting teachers - a professional development model in a distance education context.

Michelle Williams, m.williams@qut.edu.au

Research in Information Technology Group (RITE)
Faculty of Education, Queensland University of Technology, Australia

Introduction

Encouraging teachers to use computer technology is a constantly renewing problem in Australia. Computer education programs which injected millions of dollars into machine placement in schools have a 15 year history (See Bigum et al 1987) which has not resulted in widespread use of computers within curriculum in Australia (Tinker et al 1995, Maslen 1995). It is often reported that teachers unwillingness to adopt technology as part of their professional and personal lives is a reason that low key, if any, computer education activity occurs in schools (Tinkler et al 1995, Spender 1996). At Queensland University of Technology (QUT), we have taken a bold stand in the midst of Government computer-injection projects, placing the 'Teachers first' philosophy at the forefront of program design. This has become increasingly brave but significant as the rush to connect schools to the Internet, has caused yet another cycle of anxieties for teachers who are trying to make sense of the myriad of ideas and pressures on them to 'do something' with the net in schools (Williams 1996 Bigum 1995). The programs discussed in this paper demonstrate clearly how important it is to connect teachers to each other, instead of believing the usual Government rhetoric which means little more than connecting school buildings. (Williams 1996)

The problem is not only that teachers are not using technologies per se. The issue is bound in the lack of opportunity for teachers to understand the technologies which they are taking into their classrooms. It is crazy to expect that teachers who do not use technology personally, have any deep understanding of their significance in the changing circumstances being created and accelerated by the global computer networks which will become increasingly prevalent. Although connection to the Internet is considered to be yet another computer initiative, it has placed attention on the age old problem of decreasing recognition of the attitudes of teachers to new technology initiatives.

Some professional development programs in computer education at QUT have been developed to help teachers understand technology differently. They have been developed in the context of changing economic and political structures in Queensland which have seen an emphasis on distance education as a delivery solution to scattered groups of teachers. This coupled with the coincidental determination to connect schools to the Internet, has created opportunities to provide some teachers with professional development programs which immerse them in the technologies they are seeking to understand from a cultural, social and economic, as well as pragmatic context.

In describing these professional development programs, this paper examines the assumptions which underpin the design of the programs. The paper points to research which has been testing the assumptions of the program creating a basis for some discussion of the design issues for computer education and computer studies professional development programs conducted for distributed teacher communities.

The programs

QUT offers two programs simultaneously for two groups of teachers. The Information Processing and Technology Professional Development Program aims to retrain teachers to teach the subject matter of the two senior secondary subjects, Information Processing and Technology (IPT), a complex theoretical subject about information and computer science and Computer Studies, a course with embedded national vocational education modules. The second program, Computers in the Curriculum (CinC), aims at providing primary and secondary teachers with knowledge and skills to make decisions about the use of computer technology in curriculum. In both these programs, teachers undertake units from a Graduate Diploma of Education (Computer Education) and participate in a professional development program. Both aspects of the programs are conducted using distance education strategies.

In the professional development component of the program, teachers are integrated into the communities of the Internet. Electronic mail becomes the management device for the program and the strategy for invoking dialogue between the teachers and between these novice teachers and their more experienced peers. Thus the program begins with intense training in connection to and use of the Internet. The teachers are encouraged to build a local support network and to identify online and local expert mentors to support them as they learn how to participate in this environment. The teachers attend local connection workshops where practical, and take part in teleconferences which build the relationships to encourage online dialogue. As the program begins, teachers are provided with paper and computer-based study materials and expected to participate in online activities around the subject matter of their coursework. The program aims to integrate the methodology of study into the lives of these teachers, rather than treat the technology as an extra thing to do.

Drawing these teachers into the computer education community in both an online and face-to-face sense is integral to changing their understanding of how this professional community sustains its professional knowledge and practice. Thus these teachers attend three and two day residential programs where experienced teachers tell them about the new ways of working and learning. The teachers also attend the computer education conferences of QSITE throughout the state and take part in the online community which sustains the organisation. The teachers are provided with one day teacher release per fortnight to visit the schools of local expert mentors, to participate in online activities and maintain their study schedule. They are encouraged to make use of the time and the program to build a way of working which will sustains them beyond the timeframe of the program.

Behind the scenes

These programs are different to traditional professional development and coursework programs that the program developers had researched or built before. With the clear determination to provide an atmosphere which would help teachers understand the technologies they were using and teaching about, the programs were centred around the development of professional communities as a place to learn and a place for teachers to engage in professional dialogue about their practice. This strategy enabled teachers to immerse in the use of technology in a way that drew attention away from the artefacts. The program developers predicted that this context for professional development might have enabled teachers to develop a more broadly based understanding of the curriculum they were teaching their own students. Thus the program design resulted from the strong rationales and assumptions from literature and experiences in distance education and professional development.

The developers of the program were influenced by the work of Lave and Wenger (1991) who identified that a community of practice within a profession, could only be achieved by active participation within the text and conversations of the community, as opposed to peripheral and passive positions. This required strategies which 'forced' teachers to participate rather than sit on the outside reading literature and thinking by themselves. This complemented the beliefs that learning is a social activity and that for teachers particularly, critical reflection through dialogue within the peer community was an appropriate forum for thinking aloud and with others. (Day 1987, Modra 1991). Electronic mail provided the means to achieve this with a geographically dispersed cohort of teachers.

Within structured activities, the teachers participated in online debates, from which they write reflections of the subject matter of the discussions and the process they undertook. Online guests, more experienced connected teachers and lecturers provided stimulus for discussion and nurtured the teachers in expressing 'ideas in progress' and refining them online in a public place. The teachers were encouraged to comment on the ideas of their peers and to question rationales and conclusions. Working with ideas and reflections of others was inherent in the academic and professional development elements of the program. Teachers could not work alone in their classrooms or studies. They could not simply articulate their own beginning opinions. They needed to map the changes in their ideas and identify what influenced the changes in their perceptions and attitudes. This same reliance on the learner community was integrated into learning how to participate in the community. The teachers were expected to learn more about the technology by asking for technical and curriculum help online and to broaden experiences by joining into other professional conversations on Australian and state Internet list communities (oz-teachers, forum and qsite-community). The technology was also the organisational conduit and communication mechanism of the program. Reading email every day became vital to participation. As one teacher said during research programs reported elsewhere in this paper, 'I did not start a new course, I found a new lifestyle'.

Distance education theory was drawn upon heavily in the design of the program. Juler's Interaction network model for distance education (1990) provided the understanding that learners in distance education programs need to build a personal network of people who support the learner during study. Thus in this program, which required that students take responsibility to overcome technical and other logistical issues, local and online helpers became an identifiable structural element, a part of the interaction network built around the program. This building process was nurtured early by teleconference ensuring the process of interaction with others became a prominent behaviour in the program. The teleconference sessions solved immediate problems and established strategies for solving further problems. Juler's model for distance education also provided the rationale for encouraging teachers to build a interaction network for their professional development, reinforcing the message that professional development was a lifelong learning activity for the teacher, a way of participating in the professional communities which surrounds computer educators. Thus Juler's model explained how important it was to integrate these teachers into their own and other communities of practice as a long term strategy. As a specific activity, teachers were asked to identify the professional online and face to face communities which would influence their understanding of the curriculum they were teaching, the technology and their way of developing professional attitudes and practices. Linking teachers to other communities online became yet another rationale for integrating these teachers into the communities of the net.

This was fortuitous because we wanted teachers to have a much deeper understanding of how professional communities worked in the circumstances of the Internet connected world and we needed teachers to understand the professional communities and directions of the information and communications technologies industries in particular. The subject matter of the new syllabuses in computer studies required teachers to understand these stories from an insider's perspective. Understanding the net was also important. We wanted teachers understand the significance of the first hand stories spun within the Internet and the stories told by other texts and media. We wanted these teachers to engage in reflections about the new space which is being dealt with in schools as just another technology, in ways that would help them help their schools make sensible curriculum, professional development and technical decisions. The programs core philosophies embedded within a distance education program provided a natural framework for immersing teachers in the culture of the online communities they needed to teach about.

Researching the programs

The distance education context of this program provided the foundation for research about the meanings of distance in a program supported by computer mediated communications. Whereas distance education environments 'emphasise the separateness of learners from teachers and from other learners' (Williams 1995a, p.24), the program was based on notions of transactional distance (Moore 1991), drawing attention to 'the separateness of learners from ideas' (Williams 1995a, p.24) as a research question. Placing learners into the new geographies of cyberspace adds a dimension to the questions of how learners understand distance.

For the participants in this study, geographic distance was read in terms of how teachers saw themselves and the problems they needed to overcome. It was the social and cultural perception of living and teaching Ôoutside of BrisbaneÕ (the capital city in the south-east corner of Queensland) that influenced attitudes to technology and their interaction with it. Comments like Ôthings are always more difficult to understand out hereÕ were used as explanations for lack of technical understanding. Teachers from more isolated geographical areas were more determined to build a strong local support network than those who lived near QUT. In contrast, Brisbane and near-Brisbane teachers struggled for a long time on their own before asking for help and then sought support from QUT staff rather than local peers. When suggestions of local onsite help were given, these participants expressed fear of Ôbothering themÕ, a common cultural attitude for urban Australians.

The research which was undertaken was important to the team who conduct the program because it drew out an insiders view of the distances participants need to meet, in order to participate actively within a professional development program constructed within online communities. In particular, one study drew attention to the social distances that were met by integrating face-to-face events with online events.

> You know this did not work as well until we had actually met each other at QUT that weekend. I think some people have been reluctant to get online and chat. I mean you

> are fairly reluctant to even pick up a telephone and ring someone you had ever met before. I donÕt send lots of messages to those I donÕt know.
>
> (Ralph, a computer studies teacher from central Queensland)

This study also drew attention to how vital it was to structure the program in a way that forced teachers to participate.

> I did not feel part of anything. I felt like I was doing a course on my own. I canÕt believe the negative feelings I had when I started. Now I am in the little groups and I have been criticising the other writing and getting help from a fellow teacher - it's like a staffroom.
>
> (Dianne, a computer studies teacher from the coastal district, just north of Brisbane)

A significant finding from further research into this program was that teachers began to reassess the significance of working within communities of teachers and others as a professional development activity. (See Williams 1995b for a discussion of the original report.) It was clearly evident that teachers attitudes to professional development changed as a result of participating within the communities model of professional development, and that they began to understand that access to communities of teachers and others was an important way for teachers to understand the curriculum they were teaching. This is exemplified in the case of one teacher who in three staged interviews moved from 'There is no new science to teach', to, 'I had no idea other teachers would help me understand the science I was teaching', to, 'I can't understand why science teachers think they can keep up to date without looking through the science discoveries reported on the net and listening to scientists talk about their work.'

These original studies led to more detailed research. The resulting review (Lloyd 1996) examined the program as an 'example of the reflective collaboration it encourages in its students. It is a familiar recursion in a course whose medium (telecommunications) is its content (computer education) and whose students are its teachers in an online community of learners' (p. 11). The program was increasingly becoming a place for teachers to experience first hand, what it is like in the communities of the Internet and this most recent study needed to explore how teachers attitudes and perceptions to the technology and technological processes changed as a result of participating in a communications technologies rich professional development environment.

In all of our studies, there is considerable evidence that connection to the Internet was a powerful influence on changing teachers understandings of the technical and non technical curriculum they taught. This most recent research provides the most useful understanding of this. In Lloyds (1996) reflection of a teacher's shift in conceptual framework, she says

> The most significant change for Dennis came in his conceptual framework. The understanding of the Internet as a link to people, not just data, is a fundamental shift, one which counters current cultural stereotypes and marketing/promotional strategies. Using the Internet to break down cultural stereotypes and using the Internet as a means of students accessing first hand stories rather than an interpretation of that information, are powerful ideas.
>
> (p. 52)

The study identified that this shift in perception came directly from how Dennis had used the Internet for his own study and professional development. This kind of evidence has been common in all studies conducted in this program. It has shown us that immersing teachers in the program as we do, engages them in the technologies in a personal way and in a way that alters their lifestyles. It is these first-hand personal experiences which in turn shape their understanding of the significance of changing technologies more generally.

Conclusion

For teachers who are involved in use of computer and communications technologies in schools in any capacity, the issue of professional development is therefore important and becoming increasingly so. Changing technologies, new curriculum directions and a shifts in the context surrounding schools mean that professional development is more of an imperative than ever before. This contrasts to continuous poor opportunities for teachers to engage with technologies in any kind of sensible way.

AT QUT, we have developed some professional development programs which immerse teachers in the technology in a personal way. A significant element of the program is that we connect these teachers to each other and other teachers via the Internet. Thus their experience of this new idea, is not that of experiencing a new technology, but as experiencing a new way of working as a professional and a new way of learning. The research projects we have undertaken have helped us understand how important this experience of the Internet and technology is, in shaping participating teachers attitudes and ideas about new technologies in education.

Note: A full version of this paper with added detail is avialable on the CD Rom of the conference. The author would prefer people to use the original paper from the CD in all academic work.

Abstract: The Technology Enhanced Secondary Science Instruction (TESSI) Project is an innovative, field-based, longitudinal study that has developed an instructional model in which computers, multimedia technology, and related resources are coupled with elements of exemplary instructional practice to enhance student learning in Science. TESSI's success in implementing effective, technology-based learning strategies is reflected in enrollment, achievement and skills-acquisition statistics. Enrollment in TESSI's Physics 12 classrooms is now more than twice the norm for British Columbia (26% versus 11%) and the failure rate on the mandatory Provincial exam is less than 1%. Enrollment of women students is approximately 40% in Physics 11 and 30% in Physics 12 - well above Provincial norms of 30% and 25%. TESSI has also successfully addressed many essential student needs - deeper learning, knowledge backed with understanding, skills in accessing and managing expanding knowledge data bases, communication skills, group problem-solving skills and self monitoring skills.

"As administrators, we have all heard about the benefits of technology. TESSI is the first program that I have seen where the benefits are actually being realized." (Cam Gesy, Principal, Brookswood Secondary School, Langley, B. C.)

Introduction:

The need for reforms in science education have been expressed by many educational theorists and science education specialists [Gess-Newsome & Lederman, 1995; Jonassen, 1994; Jonassen, Mayes, & McAleese, 1991; Yager, 1991]. For example, Linn, diSessa, Pea and Songer concluded that "*Considerable evidence from investigations in science classrooms suggests that both the science curriculum and the role of the science teacher need reformulation.*" [Linn, diSessa, Pea, & Songer, 1994, p 7] It is important that information technology play a central role in current science education reform initiatives for several reasons. The use of technology is fundamental to scientific inquiry. Scientists routinely use technology to model observations, visualize data, access and communicate information, and control experiments. Technology is expected to dramatically improve student learning and understanding [Salomon, Perkins, & Globerson, 1991]. Jonassen et al., characterize multimedia applications as potentially enhancing the learning process by fulfilling an information or knowledge construction need of the learner [Jonassen, Mayes, & McAleese, 1991]. Linn et al., visualize the use of technology to allow students to develop, test, and refine their own hypotheses regarding scientific phenomenon [Linn, diSessa, Pea, & Songer, 1994]. But, while technology affords the possibility of producing change and educational benefits, these benefits are not automatically realized because of the technology's presence [Kimmel & Deek, 1995, Stoddart & Niederhauser, 1993]. Indeed, the promises of multimedia for instruction greatly exceed the examples of effective uses of these tools. Models for the successful integration of technology with classroom practice are essential to the restructuring science education.

Purpose:

The purpose of the Technology Enhanced Secondary Science Instruction Project (TESSI) is to develop an instructional model to help teachers enhance student learning by systematically and successfully *integrating* technology into instruction. The TESSI model is founded on the premise that if Technology Enhanced Instruction (TEI) is to become an essential part of the paradigms of science classrooms, technology applications must not be supplemental to the educational process but must be *fully* integrated into courses and programs. TEI is instruction in which computers, multimedia technology, telecommunications, and related resources are used to aid student learning and access to information. TESSI implements TEI by pairing the educational opportunities provided by multimedia technologies with teaching strategies that encourage students to locate and use knowledge rather than to accept scientific information delivered through traditional, transmissive modes. Fundamental to the TESSI model is the availability of a variety of technologies within the classroom itself: technology is used as an enabling tool to enhance teaching and learning, not as a substitute for the teacher nor an "add-on" to the curriculum.

Rationale:

Fundamental to the success of implementing educational technology are the teaching strategies employed by the teachers. Rather than trying to adapt new technology into standard teaching practices, teachers must learn how to adapt their teaching strategies to accommodate the benefits made possible by technology. Using technology to simply present better classroom lectures in a teacher centered format is not the best pedagogical use of technology. The TESSI model identifies those places where the technology can increase learning effectiveness, enable learners to do what they otherwise could not, or promote the development of significant life skills. Integration, as conceived in the TESSI model, is all-inclusive, but more importantly, all-pervasive. Advantages of integration include a) an emphasis the curriculum not the computer; b) the use of multimedia applications to enhance existing objectives rather than adding new ones - i.e. it minimizes the question "how do we make room for computers?"; c) the computer becomes a partner not a competitor - vanquishes lingering fears that teachers may be displaced by computers; d) treats the computer in a natural way, as one fundamental tool for learning and living; and e) fosters the transparency of the technology.

The twenty-first century teacher must provide opportunities for students to empower themselves as self-directed learners, with the means of understanding the constantly growing database in every subject. Technology has been posited as the vehicle for accomplishing this task. Teachers are vital in this teaching-learning enterprise. They provide the essential interface among the learner, the curriculum, and the technologies; structuring, interpreting, coordinating, and integrating the educational experiences. The TESSI Project seeks to provide a model for teachers and other educators interested in undertaking the integration of technology and learning; to serve as an exemplar of how teachers and students working together, may draw upon the tools of technology, restructuring education to meet the demands of society and the diverse needs of learners.

The TESSI Model:

The design of the TESSI model was guided by three important principles:

- the selection of technology for classroom and laboratory use must be based upon a model of implementation that makes good use of available resources to enrich instruction on an on-going basis;
- the development of an effective operational model must involve practicing classroom teachers within their own classrooms, and sustained implementation over several years; and
- the participating students must perceive their use of technology as an integral part of the normal classroom procedures, rather than as an "add-on" feature, introduced by a research program.

In 1992, TESSI equipped two Physics classrooms with a multimedia center consisting of the teacher's computer and an active matrix LCD panel and high intensity overhead projector. In 1993, eight, Ethernetted, student workstations, a laserprinter, a laserdisc player, a VCR and amplifier, a TV monitor, computer simulation software, and MBL equipment were added to each classroom. For the next two years, the TESSI project director (Woodrow) met regularly with the two Physics teachers to discuss and address technological and pedagogical issues that arose as methods for integrating the various technologies were developed. A major focus of these discussions was the identification, selection and scheduling of the most valuable learning activities and resources to achieve specified curriculum objectives. The result of this research was the TESSI model - a model that integrates various teaching strategies and learning activities into a cohesive, comprehensive program that achieves desired student outcomes; a model that provides a balanced, customized program for the students and flexibility for the teacher.

The physical resources of TESSI classrooms and the TESSI pedagogical model facilitate a non-traditional model of student learning. The curriculum is presented through a combination of technology-based activities, small-group instruction, one-on-one tutorials, and hands-on activities. TESSI students are no longer passive recipients of information, but, rather, active participants in the learning process: they assume much of the responsibility for the depth and rate of their learning. Their learning is guided by a set of interactive Study Guides specifically designed for the process. Much of the work is individually directed, with students working in small groups on interactive laserdiscs and CD-ROMs, computer simulations, microcomputer-based labs (MBL), and multimedia activities, and, when necessary or desirable, with more traditional formats including texts, labs, demonstrations, problem sets, and field work. TESSI also incorporates interactive, computer-based testing to enable both the student and the teacher to quickly identify learning difficulties and plan remediation strategies. Implementing each of these technologies requires a significant departure from the traditional procedures which characterize so much of Science instruction. Each also presents challenges to the teacher to implement on an ongoing basis. Where and how should each of these technology applications be integrated into the curriculum?

In 1995-96, five more Science teachers and their classrooms were added to the Project and work began to apply the TESSI model to General Science 8-10, Chemistry 11 and 12, and Biology 11 and 12. The addition of these new subjects is enriching the model as provision is being made to accommodate varying curricular goals and subject-specific pedagogies. In Physics, for example, heavy use is made of simulations and graphing applications; in Biology, graphics and digitized video are emphasized; in Chemistry, the MBL technology is heavily used. Each technology contributes its own benefits to the instructional model; each requires its own adjustment to teaching strategies.

Methodology:

A qualitative case study methodology [Stake, 1994] supplemented by quantitative data on participation and achievement was used to assess the TESSI model. Answers were sought to one essential question: *Does technology enhanced instruction as embodied in the TESSI model improve students' learning, attitudes and skill development?* Data was gathered over a four year period beginning in 1992 using a variety of sources including: a) video-taped observations of classroom teaching and learning strategies; b) video-taped and audio-taped interviews (both formal and informal) with participating students, teachers and school administrators; c) student questionnaires eliciting attitude and cognitive information; d) longitudinal studies of course selection and success of participating students; e) journal entries by participating teachers and researchers; f) video-taped focus group discussions; and g) results on the required provincial government final exam. The long time frame of the study coupled with the consistent use of the technology by both students and teachers were deemed essential for the TESSI model's validation. The four year period, in particular, provided the opportunity to reflect upon the implementation process, test a variety of strategies, and "fine-tune" the teaching-learning process.

Outcomes:

Outcomes of the TESSI model, after five years of implementation, have been significant. The following is a sample of the project's student results in Physics:

1. increased physics enrollment. Currently, the Physics 12 participation rate at the two schools averages 26%. This figure contrasts significantly with the provincial Physics 12 participation rate norm of 11%.

2. increased physics achievement. With their high physics participation rates, both schools maintain slightly above average standings on the required, provincial Physics 12 exams and a significantly below average failure rate on this exam.

3. increased enrollment of women students. Women students presently comprise 40% of the Physics 11 enrollment at the two schools and 30% of the Physics 12 enrollment. Again, these figures are significantly above provincial norms (30% and 25%).

4. positive attitudes towards science and technology. The retention rate of students electing to continue into Physics 12 in the two schools is 80%. This rate a strong indicator of the high student interest developed by the TESSI model.

But other, more qualitative outcomes are clearly evident as well. These outcomes include: a) the development of self monitoring skills; b) improved time management skills; c) the ability to set realistic self goals; d) increased student responsibility for their learning; f) independent learning skills; g) increased problem solving skills developed through active learning, collaborative work and peer tutoring; h) enhanced technology and communication skills and preparation for post-secondary education and careers; and i) enhanced self confidence and attitudes toward learning.

TESSI students acquire these valuable learning skills by having to assume increasing responsibility for their own learning. Although most high school students (and many post secondary students) are generally not mature enough to manage completely self-paced programs, TESSI students have demonstrated the capability of managing a "controlled" self-paced program of two to three week duration wherein they manage their own time to accomplish set curriculum objectives. Within these teacher-specified time limits, students set their own pace and select activities according to their own preference and learning styles. They can work though the unit individually or collaboratively. Practice quizzes are provided for the students to check their understanding. Optional activities are available for additional practice or enrichment. Students quickly learn that by managing their time wisely they will have the opportunity to check their mastery of unit objectives and still have time to engage in extra practice when mastery is not initially attained. On-task student behavior is high in TESSI classrooms. Students remain engaged because they can progress at their own rate and because they receive immediate feedback.

To help students become self directed and self monitoring, TESSI students establish goals for each unit that are commensurate with their ability and career goals. This goal setting process has had the benefit of having the students focus on their own achievement and success. Intra-student competition is much reduced. It is a common occurrence to hear students exclaim, "I reached my goal!" upon the completion of a quiz rather than comparing absolute grades. One TESSI student reported:

> *"I like working towards my own goal. I know my friends feel the same way - I'm not compared to the brains in the class - our marks are in our folders and nobody else sees them. I know if I'm doing well or I'm behind and can choose to work to take retests if I want to. My parents like it too."* (Sara, Physics 12 student, 1995)

The TESSI model also facilitates the development of increased problem solving skills developed through active learning, collaborative work and peer tutoring, and improved independent learning skills, time management skills and self-monitoring skills. Most of the students work in pairs or triads at the computer and at their desks. For example, one group of three Physics 12 students were observed to spend 10 minutes vigorously debating whether or not mass would affect the motion of an object sliding down an inclined plane in the simulation they were studying. These students were 'thinking' and 'talking' physics!

Initially, students need guidance in adapting to this new classroom model. TESSI teachers discuss the benefits of the new learning procedures with the students and clarify the need for students to assume the responsibility for their learning. This transition process takes time and is not without problems for some students. But ultimately, students do recognize the benefits to them personally. They understand that what is being modeled is "real world learning". As one TESSI teacher explained to students

> *"We are teaching you how to learn - how to solve problems, how to manage time, how to monitor your own learning - and, - oh, by the way, - we are teaching you Physics." (A. Farenholtz, 1995)*

A special advantage of TESSI's technology enhanced model is that it permits the linking of multiple representations of knowledge. Thus, different kinds of representations - verbal, numerical, pictorial, conceptual and graphical - can all be presented to the students and interconnected. The simulations, for example, provide multiple modes of representations by linking dynamic, pictorial images of phenomena with their graphical and numerical representations, all of which are synchronized so that the simulation's effectiveness in facilitating the process of conceptual change is maximized. Indeed, the unique advantage of using computer-based simulations in science education is their ability to provide such multi-linked representations that can help students create links among different representations of a phenomenon in their own minds. Similarly, the real-time graphing techniques of the MBL probes enables the simultaneous viewing of phenomena and its graphical representation. The graphing software also facilitates the "in-depth" analysis of the collected data while the activity is in progress. The technology is used to promote student understanding of basic ideas and concepts prior to and in conjunction with the use of abstract symbols and formulas that are so characteristic of traditional science education.

The classroom ratio of students to computers of 3:1 naturally results in students working in groups with the technology. Such grouping encourages dialogue among the students. These conversations help students to link verbal representations of concepts with the pictorial representations viewed on the screen. Grouping also promotes task collaboration within the context of computer-supported learning and helps students confront and overcome preconceptions. It is not an uncommon sight to see several TESSI students at a simulation, discussing how the physical variables interact or what will happen when a variable is changed. One group was observed to "argue" for more than 10 minutes as to whether or not the mass of an object moving down an inclined plane would affect its rate of acceleration. Such student interactions are common in TESSI classrooms. Work on problem sets is also done collaboratively although students are responsible for completing their own work. The following comments, made by two of former TESSI students, - both presently pursuing post-secondary studies in science, emphasize their recognition and appreciation of skills (not content!) learned in TESSI.

> *"The things that I think I gained from being in Mr. Spann's class were working with other people, learning to solve problems together, and learning to work on your own."* (Teri, former TESSI Physics 11 and 12 student, college sophomore, February, 1995)

> *"What I valued most was] ...the group work and the independence from the teacher, having to solve the problems by ourselves, working without being told what to do."* (Jim, former TESSI Physics 11 and 12 student, college sophomore, February, 1995)

Teaching would be simpler but much less challenging if all students learned in the same manner. Technology, perhaps for the first time, provides teachers with the means to provide for the individual learning styles of their students. Some students are visual learners, others more oral; some are linear, others more global. In the TESSI model, provision for differing cognitive styles is realized in several ways. For example, wherever possible, students are given a choice of activities to meet course objectives. Labs may sometimes be completed using traditional equipment and procedures or via a simulation. Students may complete an activity using a laserdisc sequence or by a student-led analysis of a lab demonstration. Advanced problems may be completed mathematically or with the aid of a simulation to assist in the visualization of the problem context. Many times, students will complete more than one of the choices if the concept remains unclear and nearly all students at least check in on their classmates engaged in parallel activities and compare notes. The self-paced, individualized TESSI model, supported by the technology, makes it possible for the teacher to provide and manage this rich learning environment.

Conclusion:

The results of the TESSI project support claims that learning can be enhanced through the thoughtful implementation of TEI. Further, TESSI illustrates *how* technology can be successfully integrated into daily classroom practice. The TESSI model is a means whereby teachers may be guided to quickly achieve TEI learning benefits such as deeper learning, skills backed with understanding, higher scientific literacy, skills in working with knowledge, communication skills and group problem-solving skills. The TESSI model has achieved these benefits in the two Physics classrooms consistently over a five year period and is in the process of realizing the same benefits in the General Science, Chemistry and Biology classrooms. The model has been particularly successful in attracting women students to Physics and helping the "average" student to achieve success in Physics. There is every reason to believe that similar benefits will accrue from its application to other sciences. With the needs of TEI teacher training in mind, the TESSI project is currently developing a CD-ROM based, Professional Development Program based upon the results of the last four years of research. This program is expected to contribute significantly to the impact of the TESSI project. In addition, TESSI has recently been contracted by British Columbia's Ministry of Education to establish three additional TESSI development and demonstration centers in the province by providing intensive professional training for Physics teachers wishing to adopt the TESSI model. TESSI, by invitation, is also working with Mexico's Ministry of Education on a project to "modernize" Secondaria Physics instruction through the implementation of a TESSI-based approach.

PANELS

VR: A Tool to Supplement Education

Ali Hussam
Director, Advanced Technology Center
University of Missouri - Columbia
Columbia, Missouri, USA
ccali@showme.missouri.edu

We all know that we live in an electronic age. Everyone, it seems, is "connected", "online" and "hooked up." Many students have computers in their homes, they "surf the net", they listen to musical CD's, they play electronic games, they even "chat" with strangers via the World Wide Web (WWW). And yet, in sharp contrast to this electronic upsurge, students encounter a classroom where the most sophisticated technological tools available to them include videotapes, cable television, and overhead and slide projectors. Unfortunately, too many classrooms still utilize only a whiteboard (the upgrade to the blackboard).

In what may seem like a drastic leap from the aforementioned classroom, the Advanced Technology Center at the University of Missouri - Columbia (MU) is attempting to bridge this vast gap by assisting instructors in creating computer-generated interactive immersive environments, and making them available to students in MU's Virtual Environment Instructional Lab (VEIL). By doing so, we are discovering new methods to excite and engage students in their own learning process. Learning is being brought more in line with other aspects of students' daily lives.

One of our goals at the Advanced Technology Center is to provide faculty with the tools and technical expertise to create an educational experience that is both rewarding and effective. We look ahead and research new methods to facilitate this endeavor. Virtual Reality (VR) is one of the most effective tools that can be used to achieve this goal. We currently have nine VR projects under development, with some nearing completion.

Why VR?

VR supports the creation of sensorially rich interactive learning environments. In a virtual world, all physical barriers are removed. Obstacles which prevent classes from traveling around the world and visiting other cultures are eliminated. Students can view, and more importantly, interact with scenes from the past or the future that do not even exist. All of this can be achieved in a virtual or synthetic environment. Practically any scenario can be created or simulated in a virtual environment as long as it can be programmed. Phenomena which are either difficult to perceive or cannot be detected, such as photosynthesis, can be scientifically visualized in a virtual world in a matter of moments.

Everyone recognizes the undeniable value of books and traditional lecture materials. But many faculty at MU are eager to employ the use of VR as a supplement to enrich their conventional lessons. Concepts that may be difficult to convey in the real world can be brought to life in a virtual setting. For example, Paloma, Peru, circa 5500 BC was created in virtual reality giving students the opportunity to walk around this village and to interact with objects and the environment as it existed at that time. They came away with a greater appreciation and better understanding of this world than their peers who were taught by customary methods. There is an old saying, "Tell me and I will forget, show me and I will remember, involve me and I will understand." VR helps students understand by enabling them to experience and become engaged in the lesson.

VR Projects:

BEST COPY AVAILABLE

- Virtual Environment Instructional Lab (VEIL): The University of Missouri - Columbia is the first University to have a Virtual Environment Instructional Lab with 3D stereographic HDTV, an SGI with eight R10000 processors, 3 pipe Onyx with Infinite Reality Engine and real-time digital video capabilities and a special curved screen. Students learn about such topics as Geography, Anthropology, English and Medicine in a fully immersive environment. We are also adding a six degree of freedom motion platform simulator.
- Virtual Set: The Virtual Set is a blue screen environment which utilizes digital cameras with robots, special lighting, body trackers (data suit), and a graphics-based super computer to enable live action to be embedded in virtual worlds. This technology can be used in a wide variety of applications and offers great potential for enhancing the user's virtual experience.
- A Virtual Heart with Dr. Zuhdi Lababidi: This real-time virtual reality heart beats while blood flow is animated. The model can be manipulated to allow students to explore the anatomy of the heart and also to go inside the heart and view actual heart processes such as blood flow, wall movement and valve functions. Individual heart components can be disassembled in real-time as the blood flow and heart beat continues. The next phase of this prototype will include the simulation of defective heart cases.
- Paloma World with Dr. Robert Benfer: This project is an artificial intelligence assisted virtual environment reconstruction of three ancient villages in Paloma, Peru, that were lived in from 3500 to 5500 BC and excavated by MU. The first phase of this project allows students to view realistic looking villages as presented by the instructor. The next phase, currently under construction, will incorporate QuickTime VR and a knowledge base that will be located on the Internet.
- Virtual Harlem with Bryan Carter: 1920's Harlem has been reconstructed in virtual reality for an African American Literature course at MU. Instead of just reading and analyzing literary works from this era, this prototype will allow students to become immersed and engaged in an interactive literature course.
- Intubation with Dr. Michael Prewitt: Upon completion of this project, students may learn and practice the intubation procedure in virtual reality. This will allow them to demonstrate problem solving skills for various simulated emergency conditions and patient types.
- Campus Flyover: A portion of the University of Missouri-Columbia campus has been modeled using very complex geometry from blueprints provided by MU Campus Facilities. This is the first phase of a proposed project to develop a complete VR campus to be used for promotional programs.
- Terrain Visualization with Dr. Gail Ludwig: This prototype utilizes digital terrain elevation data (DTED) to enable students to view and fly over 3D terrain maps in a virtual reality environment.
- "Making It" with Dr. Edward Brent: Virtual reality and artificial intelligence are combined to create a series of simulations designed for adolescents and young adults from ages 16 to 23. Students can experience how social constraints and their own decisions combine to affect their lives, and can even rerun the program with a different gender, race, or socioeconomic status to see the influence of those factors.

Assessment:

The usefulness and effectiveness of VR as an educational tool is only in the beginning stages of evaluation. Initially, simple surveys were developed, the results of which were extremely favorable and exceeded our expectations. We have now moved to more comprehensive assessment tools that will be used by a large number of students and will better evaluate the effectiveness of VR in the classroom. Assessment results will be tracked over the WWW and we hope to publish the results by the end of this year.

Concerns:

VR is an emerging technology that has generated not only a great deal excitement and enthusiasm, but also some worry. Some of the questions that need to be answered are: How long can a student stay in a VR environment? What is the impact of 3D stereoscopic on the user? What is the effect of the electromagnetic field generated by the body trackers? These and other questions still need to be studied and evaluated if VR is to be a viable educational tool.

INSTRUCTIONAL DESIGN FOR DISTANCE EDUCATION: HOW TO MAXIMIZE YOUR EFFECTIVENESS OVER DISTANCE

Karen Hughes Miller, Consultant, Kentucky TeleLinking Network
109 MITC, University of Louisville, Louisville, KY 40292
ksmill01@ulkyvm.louisville.edu

Mary Ann Kolloff, Associate Professor Curriculum and Instruction
Eastern KY University, Richmond, KY 40475
elekollf@acs.eku.edu

Carolyn Rude-Parkins, Director , Education Resource and Technology Center
University of Louisville, Louisville, KY 40292
crrude01@ulkyvm.louisville.edu

Successful instruction over distance is far more reliant on sophisticated instructional design than on sophisticated technology. Too often we are tempted to measure the success of distance education programming in terms of having "no technical problems". But successful technology is not the goal of distance education. Positive learning outcomes is the goal, regardless of the distance and regardless of the technology.

We three authors wish to explore ways to maximize teaching effectiveness over distance by (1) reviewing the basic components of instructional design; (2) analyzing which of these components are most affected when teaching over distance; and (3) sharing some examples of how to enhance distance teaching by using the attributes of the technology(ies) being used.

What Is Instructional Design and What Does It Include?

A lesson is typically described in three major parts. The Opening introduces the presenter, participants and agenda as well as the objectives, purpose and prerequisite knowledge. The Body of the lesson encompasses the presentation and practice. Presentation is often described as "Tell-Show-Do" or information giving-modeling-checking. Practice allows students to work toward mastery of the objective under teacher supervision. The last part, Closing, lets the teacher restate the objective and students summarize what was learned.

More detailed instructional design models such as Gagne's Nine Events of Instruction (figure 1) offer additional steps. Gagne notes that the Events are not to be considered as sequential steps, but may be used in varied sequences depending on the type of lesson to be designed. Gagne's Types of Learning and the associated lesson designs offer ways to combine and recombine the Events for different learning outcomes. The lesson design changes depending on the outcome, i.e. fact lessons are designed differently than problem solving lessons and differently still from lessons for attitude outcomes.

Today's instructional designers pay increased attention to learner centered instruction which casts the instructor in the role of mentor or facilitator and the student as an active and responsible partner in the learning process. In this mode, learners need to be able to interact with each other as they become responsible for their own learning and as they negotiate the meaning of the content. Joint goal setting and evaluation, rich learning environments and cooperative interactions are keys to constructivist learning.

Which Components of Instructional Design are Most Affected When Teaching Over Distance?

Whether using video-based or computer-based, synchronous or asynchronous distance education delivery systems, the design of the lesson must be clear and systematic. Consistency facilitates learning among students who are not in physical contact with the instructor by organizing the learning within a familiar structure.

The Teletraining Institute at Oklahoma State University has defined some design components specifically for distance learning. Humanizing focuses attention on the "high touch aspects of this "high tech" interface. Making students feel comfortable, connected and motivated is essential throughout the lesson. Message Style indicates that the lesson should be well organized and in short segments, provide variety and pacing, incorporate support media such as visuals and print materials, and use activities that involve the students. Participation, whether physical or mental, should happen within the first five minutes and frequently throughout the lesson in order to increase learning. Feedback may be written or verbal and can come from ourselves or others to confirm or correct misunderstandings or omissions.

The authors have identified other factors important to consider.
Content. Not all subjects are appropriate for distance delivery. Select the best courses or parts of courses for the medium. Within the course, work at accurately assessing student entry skills and progress in learning.

Instructor. Instructor qualities are important. Not all instructors can do it well. Select them carefully. Provide incentives for instructors to teach by distance, such as released time, incentive pay, etc. Help the instructor prepare course materials and practice the equipment to the comfort level before teaching the course - anxiety transmits well.

Interactivity. Probably the most feared and hardest to master technique, it is the most important. With experience the distance becomes transparent and real intimacy can be achieved between and among groups. Instructors often feel they will not be able to pick up the nonverbal cues that indicate students are attending. Some ways to help are to have groups select a captain who speaks for them or have proctors in the room who manage the on-site activities. Use good questioning techniques all through the lesson. In ending review, have each person say what they learned. Have a Listserv where students can discuss topics with each other and with instructor.

Technologies. The change in types of media used can throw a seasoned instructor as well as students. Video is inherently a visual medium and information needs to be presented visually. Select the best medium for the content. But, some problems may be that video tapes may transmit poorly and be jerky; the chalkboard may not be very visible; transparency film is reflective - use the master copy. Voice sound is often a problem both in volume and in understandability. Also sound in the room can be disruptive - use the MUTE function. Have resources and facilities to develop multimedia materials for use in lessons. Use Internet and the Web for supplementary materials.

Room Design. Create a successful distance learning environment. Set up the room to provide areas where different types of activities can take place. Provide for instructor and student mobility. Attractive colors, room lighting, decorations are important.

Technical Issues. Make sure technical support people are available because if it can break it will. Have alternatives for when the equipment goes down.

Success Stories - Quick Tips for Teaching Over Distance

When instructors are really secure in their knowledge of content and have created a solid instructional design, they can move their teaching through time and over distance without losing any impact. In fact, when an instructor adapts the lesson to take advantage of the attributes of the technology, they may even enhance the experience.

We all know that "talking head" television was not successful because it was not supported by a strong instructional design. But as soon as we move the camera back to include additional graphics and materials, we expand our possibilities. When we take the next step and provide for total learner centered interaction, we have truly opened the door to good teaching over distance. (See figure 2)

Some of the most dynamic examples of learner centered interaction are found when the learner(s) are given control of the delivery system. Integrated voice/video/data networks such as the Kentucky TeleLinking Network (KTLN) create an environment where distant sites not only receive but also produce images. In this environment, the instructor can design activities where distant students are called on to provide segments of the lesson. For example, if several distant sites are sharing a history lesson, each site may be asked to research and then role play how a specific character from history would react to a contemporary political issue. To keep all students engaged while one site is presenting, the instructional design can include assessments and peer evaluations. Each student has a role to play, whether on camera or off. When all students are aware of their learning obligation for that lesson, they are less likely to drift away from the lesson.

Satellite (video) instruction offers less opportunity for dynamic interaction, but presents us with the extraordinary strength of broadcast quality video as a medium of instruction. Designs for satellite instruction can maximize the immediate visual opportunities and use other technologies such as audio return (phone lines) and asynchronous communication (Internet) to support learner response. The same basic concept applies here as well - each student must be aware of their learning obligations.

One of the greatest challenges facing distance educators is selecting the best medium for each component of instruction. We get trapped into thinking that satellite courses are ALL video, or that computer courses are ALL text and graphics. We must not forget that other media of instruction can allow learners to respond. FAX, mail, and telephone (including audio conferencing) are all basic, strong, versatile tools in our instructional tool box.

In addition to the mix-and-match approach to technology, we can also apply a mix-and-match approach to the "sociology" of our instructional design. Some activities are best done by individuals, some in small groups, and some with a mentor/facilitator. A good instructional design will cover or only what goes on in the classroom, but also the learning activity outside of the designated class time. Seeing the technical and the personal possibilities as a "matrix" rather than a linear progression will expand your field of vision as you develop instructional designs.

Figure 1

Gagne's Nine Events of Instruction

1. Gain Attention - Say or show something related to the lesson topic to activate alertness. Use a story or situation, dramatic picture, animation.

2. Describe the Goal - Motivate by telling what learner will be able to do after instruction, what prerequisites are necessary and why the learning is useful.

3. Recall of Prior Knowledge - Assist learners in retrieving the prerequisites via statements or pretest. Provide self-directed ways for learners to check their knowledge.

4. Present content to be learned - Show and tell the type of display to be learned from, accenting distinctive parts. Be consistent in the presentation style in order to focus attention on pertinent information rather than irrelevancies.

5. Provide guidance for learning - Help learning and retention via diagrams, pictures, lists, memory aids; organize to facilitate long term storage. Give more guidance at the beginning of the practice and build toward independent use.

6. Elicit performance - Learner demonstrates what was learned in life-like situations. Case studies and scenarios provide realistic practice opportunities.

7. Provide informative feedback - Feedback from own observation or instructor reinforces and corrects the learning.

8. Assess performance - Test learning of the material in ways similar to the practice situations.

9. Enhance retention and transfer - Review the learning and provide additional practice in various situations and spaced review of the learning to help transfer to job.

Gagne's Types of Learning Outcomes

1. Identify Facts - present and practice information.
2. Classify by Concepts - present concept and practice classifying examples.
3. Procedural Rules or Problem Solving Guidelines - provide a problem setting and practice using rules or guidelines to effectively solve the problem.
4. Motor Skills - give realistic settings for practice of a procedure.
5. Feelings / Attitudes / Values - clarify and give practice on choice making.

Figure 2

"Quick Tips" for Distance Education

1. Think of your role as a mentor / facilitator rather than a lecturer.

2. Design each lesson in segments to provide a purposeful shift in students' attention. Extended attention to either a video or computer monitor is tiring!

3. Make at least one personal visit to each distant site during the semester. Even if you are known to most of the students, your visit becomes a special event.

4. Prepare in advance so both you and your distant students have all materials in hand for the lesson. Use UPS or other ground delivery if necessary - but do not ignore other teaching materials.

5. Enjoy the new experience and down play any technical inconvenience. You are not only teaching but also modeling teaching/learning behavior.

"The Michigan Model for Educational Telecommunications: Tipping the Iceberg"

Douglass Scott
School of Education
University of Michigan
Ann Arbor, MI, USA
djscott@umich.edu

Panel Overview

The Interactive Communications & Simulations (ICS) group at the University of Michigan's School of Education launched its first computer-mediated simulation in the Spring of 1984, and has since sponsored a number of other educational simulations which attract participants from 27 U.S. states and 23 countries. ICS's basic approach, the "iceberg metaphor," or the "Michigan model," has remained constant despite rapidly changing technology.

In this panel, Roger Espinosa will trace the historical stages of the computer interface, Jeffrey Stanzler will examine the role of university mentors in ICS exercises, and Douglass Scott will offer examples of how the iceberg metaphor shapes the role of classroom teachers.

The Iceberg Metaphor in Practice: The International Poetry Guild

ICS conceptualizes the learning experience facilitated by educational telecommunications using an iceberg metaphor. That is, the on-line communication between participants in a simulation is seen as similar to the 10% of the iceberg that remains above the water's surface. The remaining 90% of the learning experience takes place through the face-to-face interactions of students and teachers nested in classrooms around the world; interactions that are *supplemented*, rather than *supplanted*, by the on-line communications. The face-to-face component of these exercises is key to our understanding and development of computer-mediated simulations.

In practice, this model shapes ICS exercises in several ways: 1) emphasis on student-generated artifacts, 2) less directed, more open-ended student participation, 3) emphasis on student-to-student communications, and 4) scaffolding by ICS mentors for both students and teachers.

An example of this model in practice is the International Poetry Guild (IPG). Students electronically submit poems to the IPG conference where other students and ICS mentors can discuss them, offer encouragement, and make constructive comments. As poems are submitted, other participants are evaluating them for possible inclusion in their own poetry journal, a thematic collection of poems created by each class and the culminating project of each group of IPG participants. Finished journals range from the hand-made to the professional printed, but all require a great deal of time and energy to plan and execute.

IPG exemplifies ICS's emphasis on facilitating face-to-face interaction through telecommunications. Prior to submitting a poem, students would be instructed by their teacher on the genre and would practice writing different types of poetry in class. Creating a poetry journal involves editorial decisions, page layout, artwork, photography, and, in some cases, marketing as the journals are sold to generate funds to pay for the next IPG session. Thus, while IPG is facilitated by the electronic transfer of poetry and on-line discussion, the bulk of the participants' learning experience takes place through face-to-face interactions in the classroom: Interactions that would be invisible simply by reading a transcript of the on-line communications.

Making the CMC Process More Visible Through Technological Innovation

Roger Espinosa
Office of Instructional Technology
University of Michigan
Ann Arbor, MI, USA
roger@umich.edu

Introduction

ICS's iceberg metaphor is about communication, and the tip of that metaphorical iceberg is computer-mediated communications. This guiding model assumes that a rich and complex set of interactions are taking place in classrooms that remain largely invisible simply by reading the on-line communications. Based on this assumption, we have attempted to create on-line environments that bring more of these interactions "to the surface." In one sense, this means providing places in the on-line environment that allow students to show some of the fruits of their face-to-face interactions. One example is putting the International Poetry Guild's participants' poetry journals on-line for all to read. Another way we work to accomplish this is to develop ways for the user to access outside resources, or for them to bring outside resources into the exercise. This capability has only become possible with the recent migration of ICS's exercises to the World Wide Web. The path we took, from CONFER II to the Web, deserves some explanation.

Past, Present, and Future Directions

ICS began on the University of Michigan's CONFER II mainframe conferencing system that offered a command-line interface. While limited, CONFER II offered item/response threading, a rare feature in even today's CMC environments. After 10 years of service, and changes both in classroom access as well as the University's computing environment, the end of the mainframe was near, and we began exploring alternative environments to support our exercises.

The first step was Visual Confer (VisCon) which had a limited ability to digest new articles. This was an advantage as it could be configured to support the goals of a particular exercises. Connectivity was another issue. Unlike CONFER, where schools could reverse phone charges, VisCon relied on schools having "Telnet" access, which proved both rare and unreliable. In addition, the digest feature didn't work well in practice and it was based on a "one computer-one classroom model" which wasn't in sync with the various end users' situations. We briefly experimented with an e-mail based digest system which offered the broadest connectivity, and provided extended support for digests which allowed it to meet our simulations' needs. However, limitations included the lack of an intuitive way to track discussion threads, as well as the difficulty of supporting the wide variety of e-mail formats used in classrooms.

We are currently experimenting with a World Wide Web/E-mail system. While this technology is relatively new, and changes rapidly, it builds upon most of the advantages of previous models, while avoiding some of their limitations (although like any new technology, it presents its own challenges). This model provides all of the advantages of the former e-mail system with three important advantages:

- outline method of seeing complete threads
- digests via the WWW (able to see the new posts since your last visit to the site)
- for e-mail users, richer posts (HTML, graphics, etc.)
- for WWW users, richer posts, links to outside resources, etc.

Mentor Issues: Examples from the International Poetry Guild

Jeffrey Stanzler
School of Education
University of Michigan
Ann Arbor, MI, USA
stanzler@ics.soe.umich.edu

Introduction

Much of the previous discussion of ICS's iceberg model has served to focus attention on the importance of fostering the participants' face-to-face interactions. This is an important goal, but as we shift our focus, we should not lose sight of the on-line interactions that connect the various participants. One important group in this process is the mentors, University of Michigan students specializing in a simulation's content area. In this presentation, I will focus on the role of the mentors in the International Poetry Guild (IPG), discussed above.

Mentor Challenges in the IPG

There are a number of issues that come up for the IPG mentors that center around how best to nurture creativity in others. I start with the assumption that, even if it is done under duress, it is a brave thing for a teenager to share her/his work with a worldwide audience of peers, teachers and mentors. It may also be exciting, gratifying, too abstract to get one's brain around, or even (God forbid!) a real "so what?" For argument's sake, though, let's assume that the majority of the students have some personal investment in the creation and sharing of their work, even those that would tell you they hate poetry. We should also assume that the work of these poets is frequently (and understandably) characterized by a lack of sophistication, by a heavy reliance on rhyme, and by a tendency to focus on "big" topics like love.

There are a couple of issues which I think are somewhat unique to this type of interaction. One centers around the mentors' relationships with the poets. One teacher on our network told me recently that she's often had the experience of teaching her students something about poetry and having it fall on "deaf ears." The next day, as she tells it, a communication comes from a mentor that makes the same point and, voila, it clicks! Now, what is described here is surely more complex than what this teacher relates. She is an exceptional teacher with an amazing rapport with her students and I'm sure she is underplaying her impact on her students.

This story raises an interesting issue. The mentors, in this context, have several advantages. For one, they (in contrast to the teacher) have no grading responsibility with regard to the poets. They are, however, typically far closer in age to the poets than are the teachers. They know, to paraphrase one teacher, that the Red Hot Chili Peppers are found in a music store and not a supermarket. Finally, the mentors have a clear authority in the exercise; they are the primary source of response to poems and, whether we wish it or not, judgments about them. They are also here at the University of Michigan, and this fact alone lends an authority to their words, deserved or not.

Conclusion

ICS mentors have been an indispensable part of our exercises from the beginning. My role as Staff Coordinator has brought me into contact with all our mentors for the past several years and I believe their contribution is crucial to the effective operation of our exercises. Our mentors exhibit numerous skills, content-based and interpersonal, and the role of mentoring on-line conferences is major area of research interest for me.

Teachers' Role in the ICS Model: Examples from Middle Schools

Douglass Scott
School of Education
University of Michigan
Ann Arbor, MI, USA
djscott@umich.edu

The Role of Teachers in the Iceberg Model

The iceberg metaphor was explained in the overview to this panel discussion and the International Poetry Guild (IPG) was offered as an example of this metaphor in practice. IPG is exemplary of how the learning of groups of students nested in classrooms is facilitated by computer links with their peers. IPG, like all other ICS exercises, progresses through student-generated artifacts (e.g. poems, messages, discussion) rather than through materials supplied by ICS. Classroom teachers are essential in guiding their students through preliminary writing exercises, helping them organize their own Guild, and supervising the creation of their poetry journal.

The notion that much (the metaphor's 10/90 split is a heuristic emphasizing the importance of in-class interactions) of the students' learning takes place within their classroom empowers teachers by acknowledging the importance of their efforts in this process. Unlike a distance learning situation where student and teacher are separated, teachers participating in ICS exercises work directly with their students and the products of these interactions are transmitted to other groups working in a similar fashion. Our simulations are predicated on this relationship as they emphasize and foster student-student and student-teacher interactions rather than asking them to rely on the exercise for exercise content.

Teachers and Technology: Scaling the Learning Curve

The push to bring schools on-line places a great burden on teachers, most of whom have little or no experience with computers or telecommunications and many struggle to include these technologies in their classes. One veteran middle school teacher with whom I spoke describes the difficulties she encounters in trying to incorporate these technologies into her teaching:

> [using computers and telecommunications] doesn't come naturally. I'm an old dog learning new tricks. But I love working with kids and I like to teach creatively and to teach relevantly and I see telecommunications as a way of communicating for the future, not just for schools, but all over the place and I feel if there's any way that I can get the kids participating in this and aware of it, that I'm doing them a service. But I have to struggle with it..."Mrs. Patterson," 7th grade science teacher

Many teachers with whom I've talked are in a similar position. They are intrigued by the potential of the Internet to bring outside resources into their classroom, but are apprehensive about how they will integrate these resources into their curriculum, and what is their role in this process.

This discussion will address my observations and experiences with classroom teachers as they work to incorporate telecommunications into their teaching. This will provide but a brief glimpse into the actual engagement of teachers and students with ICS's exercises. However, these examples serve to inform our thinking about computer-mediated communications in instructional settings, and push us to continue to develop exercises that foster our participants' face-to-face interactions.

SHORT PAPERS

AN INSTITUTION STRATEGY: DEVELOPMENTS AND EXAMPLES

Alan Amory, Multimedia Research Group, Biology Department,
University of Natal, Durban, 4041 South Africa
amory@biology.und.ac.za

Abstract: Institute-wide strategies for development of interactive teaching materials depend on use of standards, appropriate tools and evaluation of pilot projects. HTML was selected as the foundation for all developments. Internet Explorer and Navigator are restricted as they are limited on the Windows 3.11 platform, have no integrated search capabilities and do not support linear browsing along authored routes. INK was developed to solve these problems. Here authors structure courseware in a hierarchical manner by adding HTML pages and associated index terms. INK was used to create a HTML tutor and a courseware module (Plant Sex). The tutor was successfully used to teach HTML to staff and students. Plant Sex, which includes animation (to demonstrate difficult concepts) and sound (for pronunciation of biological terms), was developed to support student groups, working in a contructivist classroom, in answering worksheets. Students enjoyed the course, found the software useful and performed better on examination.

Introduction: During the past three years the Multimedia Research Group of the University of Natal has researched the use of multimedia as a teaching aid and is involved in defining both hardware and software standards. The rapid and impressive advances in the delivery of multimedia via the World Wide Web could provide a platform for University-wide delivery of teaching materials. In this paper I will describe the strategy, illustrate the software developed to realize the strategy, and evaluate a course authored with this system.

Strategy: A number of objectives were defined and include: Adherence to international standards for delivery of teaching material; Support for Microsoft Window platforms (versions 3.11, 95 and NT); Use of a standard and easy-to-use interface; Easy maintenance of developed courseware; Delivery on both the Internet and intranets; and Rapid development and deployment of support tools (software). Hyper Text Markup Language (HTML) was selected as the standard for all interactive courseware development. To allow both hyperlinking and browsing of the material in a more linear fashion, to provide an outline of the contents and use of keyword- and free-form text searching, an authoring system was developed. Associated with a core database is the authoring system (used by faculty) and delivery system (used by students). In the following sections I will describe the tools used to create the system, the authoring and delivery programs and a HTML tutor. Thereafter I will discuss a research project that used these tools to create courseware.

Authoring System: INK, coded the Borland Delphi, consists of three work areas: toolbar, hierarchical control and HTML viewer. Commands for file manipulation (new project creation; opening of existing projects; saving of projects and publishing of documents), creation and manipulation of the project-contents (insertion and deletion of HTML files; keyword, record title and filenames editing; ordering of pages), HTML code manipulate (creation of a new page; editing of existing HTML code) and navigation tools (contents page; history; search; last page visited; previous page; next page; zoom control) are included.

Student Viewer: The viewer contains a toolbar and the HTML display object. As no menu is available, all navigation is via the mouse using the hyperlinks or the toolbar button commands (Exit, Print, Contents, History, Back, Previous Page, Next Page and Zoom). The software provides search capabilities where pages can be found using a dialog box with a hierarchical display of the contents, via authored keywords or by full-text searching.

HTML Tutor: To help University students and staff in developing courseware using HTML, an interactive tutor based on the INK system was developed. The user interface is identical to the INK viewer except that an additional component consisting of an text editor control associated with an HTML viewer control has been added to allow users to experiment interactively with HTML tags. The tutor was well received by both staff and students and demonstrated the power of the INK Development System.

Research Project: This program was initiated to: Evaluate the efficacy of a hyperlinked document as an educational support tool; Remove the artificial boundary between theoretical and practical work used in the traditional system where theory is taught in a lecture room and practical work in a laboratory; Test the delivery of teaching material developed using INK; and Illustrate alternative teaching techniques to the Department of Biology in the first instance.

Application Design: In the past a course on Fungi, Algae and Lower Plants consisted of didactic lectures and laboratory exercises. The new course was designed to place the student at the centre of the learning process and consisted of worksheets and a graphical hyperlinked document used as a support tool. The course integrated theory and practical work. Worksheets, integrating both theory and practical work, were answered by students working in groups supported by facilitators (during contact time) and the computer document available on the student Local Area Network (after contact time). The hyperlinked document, authored using INK, served as source material to the worksheets and provided definitions to all the terms used. Animation was used to explain difficult concepts, and sound for the pronunciation of biological terms. To assess student attitude, a course evaluation was conducted. To determine the effect of the change in teaching method on student performance examination results were compared to those obtained in previous years and results from the plant reproduction course compared with other modules within the course.

Research Findings: Generally students enjoyed the course but found that they needed more time to complete the tasks and would have appreciate more individual help. Students reported that the use of worksheets was appropriate, in that it allowed them to identify concepts they did not understand, encouraged active participation, enhanced understanding and made revision easier. However, they also felt that the worksheet problems were too difficult. Students found the computer programs useful and easy to use, but some would have preferred written notes. During the three years that the new course has run (1994-1996) there appears to be an increase in student performance (not statistically significant). Also, in 1996, students obtained higher marks in the constructivist course compared with other traditional instructivist courses. A change in teaching method, therefore, did not significantly alter student performance but there was an increase in the mean mark obtained.

Conclusion: An HTML-based authoring and deployment system is cheap to implement and adheres to international standards for delivery of interactive courseware. The use of Rapid Application Development tools allows for speedy implementation of the INK development and delivery systems that run on all current versions of Microsoft Windows. A modular approach used to develop the software allows for easy maintenance and extensibility. Using HTML as the base for delivery of courseware permits material to be created for both intranets and the Internet simultaneously. The use of software in a constructivist-teaching environment was successful as students appeared to enjoy the course without there being any loss in performance. This finding supports the notion that software cannot teach but can be used as an educational tool. The integration of theoretical and practical aspects of the course into one coherent whole was appreciated by most students. The INK development systems proved useful in the implementation and delivery the software. Redesign of this and other courses has stimulated discussion within the Department on alternative teaching philosophies and methods.

New Information Technologies and Rural Societies

David Arnold - Education Consultant, Education Technology Specialist, DAAC's Learning Systems, Canada,
davida@pfdesigns.bc.ca

Abstract: Comparisons of new information technology to the telephone, the printing press and the steam engine, highlight expectations of marked changes in culture, community and society. This paper examines three rural communities in various stages of change, as it relates to Internet inception and evolution. Firstly, we investigate an Australian community that is looking to new information technology as a potential solution to their stagnating society. Secondly, we expose a Canadian locale that is dealing with the birthing pains of Internet introduction. Finally, we examine a population that has lived with the Internet successfully for three years and is moving through adolescent challenges with expectations of maturity and self-sufficiency for this new information technology.

This qualitative study will offer emergent themes that highlight potential pitfalls and provide best practice suggestions for successful introduction or harnessing of new information technologies in rural communities.

Introduction

"When historians look back at the latter half of the twentieth century it might well be remembered less as the time man walked on the moon, and more as the time we gave birth to the Internet." [1]

Presently, our own new information technology, the Internet, is undergoing an evolutionary process with the formation of its own rules, habits and resulting societal changes. This paper provides a snap shot of rural communities in two countries, traveling this evolutionary road. It is my intent that this study will provide practical assistance for Community Development Officers (CDO) in rural communities. Having worked as a CDO in rural Australia and a Consultant in rural Canada, I empathize with workers seeking rural regeneration, diversification and general community development. These emergent themes may highlight potential pitfalls and provide best practice suggestions for successful introduction or harnessing of new information technologies (NITs).

Background to the Paper

The fact that this study is still in progress dictates that this copy will be introductory only and somewhat disjointed. DAAC's Learning Systems is an independent research and training company that will provide the final report and recommendations in July; both to the Department of Family and Community Services, Australia, and the Community Economic Development Centre, Simon Fraser University, Canada. The Australian government is looking at innovative ways to assist and encourage rural community development while the Canadian organization is looking at application of NIT's to regenerate democractic, pluralistic, civil societies in the Czech Republic.

Four basic issues to be looked at are: Whether New Information Technology's (NITs) tend to segregate groups by specialized interest; whether NITs foster class/socioeconomic exclusiveness leading to issues typical of non accessibility, non-participation, and non-representation in pluralistic democratic processes; whether NITs indifference to space-important issues such as bioregional ecology frustrate community building; and , whether or not NITs make for vulnerability to subversion and top-down control.

[1] Cochran, Andrew in association with The Discovery Channel (Canada), (1996) Life on the Internet - Documentary # 1, "Understanding the Internet", Internet Site, http://cii2.cochran.com/understand/uti.html

Methodology and Research Tools

My approach to this analysis of rural communities has been decisively qualitative with questionnaires, interviews and informal discussions providing the bulk of the data. Emergent themes have been collated from transcripts. After initial contact and familiarization with the community I set up appointments for interviews and discussions and/or mingled socially with community members.

Communities and Access

Australian Community

The Australian community studied epitomizes all that is mythologised about rural Australia. In the imagination of Australians, we see the 'bush' as the backbone of our sunburnt country. This consumer image portrays "healthy produce, wholesome individuals and a pleasant relaxed lifestyle" [Stehlik 1996]. A study of the area however suggests produce that has lost its 'flavour', stubborn individuals, and a stressing lifestyle. The imagined backbone of rural Australia has developed a degenerative spinal condition. The forces that held it strong and resilient now hinder its turning and redirection. For this backbone to continue to support any activity it must flex or crumble. Diversification through empathic community development is the solution.

The farming community is reeling from the combined blow of climate and the economic demise of their primary industries. The township communities that rely on primary industry money are also feeling the pinch with fewer demands for their services and products. Civic pride is stretched as streets become patchy and services move away. [Volgyes 1980] saw a bleak future when he commented that there seems to be little practical reason for many of the country's small towns to survive. In the sixteen years since this remark, many have been amazed at the persistence of the rural sector. It is however no longer enough to merely persist, stand, and survive. In this state, a blow, such as the drought in Australia, unmasks the frailties and threatens extinction. For there to be a real future with viable options, rural communities must flex, diversify, tap into fresh sources of vitality, and find their new niche in an evolving global community.

Rural towns need to attract alternative industries or look at marketing the Australian Bush image to keep themselves viable. [Martinez-Brawley 1990] proposes a model of community development that suggests the Community Development Officer (CDO) is "an agent for change, working with the community, identifying and using the communities resources and energies for the benefit of the whole". As CDO for this district I worked with community members to devise a list of possible enterprises and options to persue. Included in this list were: tourist ventures such as a heritage centre and rural market; training options such as diversification field days and smart farming seminars; attracting new industries such as a meatworks and light manufacturing; encouraging new information technology to create new jobs and attract telecommuters. The Australian community did not have access to the Internet at the local level. Individuals had heard about the potential benefits and were looking into the necessary advances needed to entice the tele-commuter to their area.

Canadian Community Number One

The first Canadian community studied has a population of 1,500. The nearest large center (over 50,000) was 3 ½ hours by road. Forestry accounted for the majority of jobs in the area with tourism increasing steadily. A 'logging camp' mentality prevails with a feeling of impermanence still noticeable. Diversification plans have been instigated by a proactive council and their Economic Development Committee which has taken an active interest in the supply of Internet services.

The Internet Society intends to offer training and mentoring at the Learning Centre and throughout the community as well as introduce youth, community groups, entrepreneurs and local businesses to the opportunities on the Information Highway and to explore the tourism and economic development opportunities that exist with access to this information highway. The society came about when a partnership was formed with Industry Canada, educational institutions, local business and government, the library, community service groups and community media to highlight benefits of the information highway for area residents. The Internet Society now provides callers in the area with affordable access to the Internet through a high speed data transfer system located within the community. This access had been available for one month at the time of study.

Canadian Community Number Two

The second community studied has a population of 4,500. The nearest large center (over 50,000) was 1 ¼ hours by road. Forestry accounted for the majority of jobs in the area with agriculture coming in second. The community has a feel of self-reliance and pride. A resilient pioneering spirit prevails and has spilled over into innovative areas with technology embraced to reach goals.

The Access Network Organization is a community-based not-for-profit association aimed at providing a shared interactive resource through a local Internet connection. This Network provides service to a huge area that includes seven farming and forestry communities spread out over 1,500 square kilometres. More than a few public access sites were needed to effectively serve this area. The Access Network solved this problem by establishing a mobile site that travels to the ranches, community centres, and mills within the area. Training sessions are provided on request.

The local School District has established a thriving electronic busing system that has been operating since 1994. 490 students, mostly in isolated areas, receive their daily instruction through NIT's.

Conclusion

As the Internet itself continues its evolution away from its linear beginnings towards a flowing interactive and creative medium it will be able to address more easily the questions of enhancing a civil society in developed market economies. Snapshots of NIT birth and development in communities may indeed speed up this evolutionary process as we take the time to reflect and reconceive.

This study is ongoing and therefore incomplete. The penultimate report shall be presented at the conference in all its multimedia splendor with the final report available in July.

Abstract

Student portfolios have been widely used for years in some areas of education.This paper discusses a technological enhancement of traditional portfolios, electronic CD-ROM portfolios. Fourteen students completed the first offering of Industrial Studies 189*: Document Production and Control Seminar* during the Spring 1996 semester. In evaluating the final electronic portfolios, the work fell into three distinct groupings. The first set maintained the paradigm of the traditional, paper-based resume and did not include many details nor multimedia features. The second group maintained the structure of the traditional resume but expanded each section including multimedia features such as videos, sounds, and/or graphics. The last group broke with the traditional paradigm and recreated new structures.

Electronic Portfolios as an Assessment Tool

According to Crouch and Fontaine [1994 p. 306], the term "portfolio is defined as a selection of assignments that a student has consciously assembled from a number of pieces produced over a semester or some other period of time." In the elementary grades, portfolios have been found to be effective in helping the teachers make instructional decisions in the classroom [Dewitz, Carr, Palm, & Spencer 1992]. A review of research in the use of portfolios in mathematics learning showed that they enhanced students' mathematics learning and communication about student progress among teachers, students, and parents [Cicmanec & Viechnicki 1994]. However, in the Vermont statewide performance assessment of portfolios, this positive impact on instruction contrasted with empirical findings about the quality and reliability of performance data the program gave [Koretz, Stecher, Klein, & McCaffrey 1994]. In the university setting, portfolios are being suggested and used as a method for assessment in teacher education because they allow both the potential teacher and the educational professor to address issues in greater depth [Richlin & Manning 1996]. In addition, they have been used in other areas including writing, education, and business communication [see Bacon & Bloom 1995; Reilly et al 1993].

Results

Fourteen students completed the first offering of Industrial Studies 189*: Document Production and Control Seminar* during the Spring 1996 semester. In evaluating the final electronic resumes, the resultant electronic resumes fell into three distinct groupings: traditional resume—4 students, extended traditional—4 students, and full multimedia—6 students.

This first group of electronic resumes maintained the paradigm of the traditional, paper-based resume and did not include many details nor multimedia features. In considering the resumes in this group, one can see that the designs are simplistic with little interaction or special effects.

1154

The students in this group maintained a "traditional, paper-based" paradigm despite authoring in a multimedia environment. In general, they included the exact same categories as their paper resumes and limited the information in each section to that found on a traditional resume. Although most of the students in this group fulfilled the minimum requirements for this assignment, there was little attempt to include additional features or multimedia elements into their electronic resumes.

The second group of resumes maintained the structure of the traditional resume but expanded each section including multimedia features such as videos, sounds, and/or graphics. The interface designs of this set of resumes also were simplistic with few features and details. In this way, they were similar to the resumes in group 1. This student added more multimedia features to his resume than did students in the first group.

The last group of resumes broke with the traditional paradigm and recreated new structures. When one considers the subsections of resumes in this group, they are more complex than the other two groups. Most of them include subsections (or categories) in each section. This allows the user to have more options and make more choices. Instead of having a simple screen or buttons to show each subsection, the student used pictorial or interactive approaches.

Educational Importance

The major theme throughout this paper deals with the infusion of high technology and multimedia instructional modes into the professional educational curriculum. This paper showcases one technique for promoting student learning and achievement. The development of portfolios by students is not a cursory process. In order to be effective, portfolios require students to become self-reflective and view their work as a whole rather than as unrelated pieces. Electronic resumes, as natural technological outgrowths of portfolios, can expand this active process further by encouraging students to express themselves visually as well as in written form. In addition, this study shows that the use of electronic portfolios brings learning that is interactive and socially based. Although unplanned by the instructors, students freely collaborated with each other, both in designing the multimedia as well as critiquing the content. This student-directed, collaborative learning possible is the best outcome of this activity.

The Discourse of Online Learning: Cognitive and Interactive Dimensions

Abstract: It is our contention that appropriately designed educational computer conferences can be an example of institutionally sanctioned space where the discourse of science represented by scholarly texts is dialogically interpreted by communities of learners [see Wertsch 1991, Wertsch and Toma 1995]. Therefore, one of the central questions facing researchers of computer conferencing proves to be: Under what circumstances do learning groups engage in a dialogue containing the cognitive patterns consistent with the instructional goals in the particular situation? How can such a dialogue be successfully nurtured? In this paper we set out to explore these questions by devising taxonomies of descriptive categories, capturing the diverse cognitive acts and interactive moves performed in the course of online group discussions. We believe that analysis of students' online discourse based on these categories can provide educators with awareness of the different choices available in designing and directing computer conferences towards their desired outcomes.

Goals of This Study

Our study focuses on computer conferences constituting a component of undergraduate and graduate level university courses in the areas of new media of communication and educational technology. The required learning activities in the courses we examined consisted mainly of critical discussion of required readings in the respective areas. The instructional goal for the online conferences was to engage students in critical thinking on problems encountered in or derived from the literature, that is, to generate personal and collective meanings on the basis of critical dialogic engagement with the content of the readings. Furthermore, thinking on these problems had to be performed collaboratively, drawing on the personal experiences and reasoning skills of all participants. Thus, critical thinking and collaboration emerged as two central concepts characterizing the normative orientation and subsequently, the goals and expectations of the instructors teaching these courses. It was implicitly assumed that critical thinking and collaboration would reinforce each other: more collaboration would bring forth a higher level of critical thinking on the part of the group as a whole.

Choosing these two concepts and the relationship between them as the centre of our interest, we sought:

(a) To devise taxonomies of descriptive categories, capturing the diverse (1) cognitive acts and (2) interactive moves performed in the course of online group discussions with a view to gaining a better understanding of the processes of critical thinking and collaboration and evaluating the conference in these terms.

(b) On the basis of these taxonomies, to identify cognitive and interactive styles exhibited by individuals and groups involved in online conferencing.

(c) To identify systematic relationships between:

- styles of group interaction and cognitive processes;
- learning activities and instructional designs on one hand, and observed cognitive activities and interactions, on the other.

Methodology

We have used as our source of data the transcripts of three online conferences carried out over one-week periods of time by student groups consisting of 5 members each, and supported by the VirtualU (a Web based educational environment developed at Simon Fraser University, Burnaby, B.C. Canada).

Qualitative and quantitative discourse analyses focusing on the functional aspect of utterances have been our main methods. Comparative analysis of the distributional structures of interactive moves and cognitive acts performed by different groups in different learning situations has been also employed.

Results

Building on previous theoretical and empirical work dealing with analysis and evaluation of educational computer conferencing [Harasim 1991], [Henri 1992], [Riel & Harasim 1994], [Newman, Webb & Cocharne 1995] and our own observations, we have created working sets of categories characterizing the two important dimensions of online discourse related respectively to critical thinking and collaboration: the cognitive and the interactive dimension. It is our premise that if we manage to describe the structure of cognitive activity performed in a conference, we will be better positioned to understand when this cognitive activity can be characterized as critical thinking. Similarly, if we manage to describe the structure of interactions observable in a conference, this would help us to judge whether and to what degree this conference has stimulated collaboration.

Each utterance pertaining to online educational discourse, we argue, is charged with either cognitive or interactive function, or both. Cognitively charged “speech acts” [Austin 1962], [Searle 1979] deal with certain operations performed on the subject matter under consideration: identifying problems, stating positions, questioning positions, etc. Interactively charged “speech acts” establish a relationship between other conference participants and the speaker: acknowledgment, support, disagreement, etc. The individual categories pertaining to each of the two dimensions have been derived from existing theoretical models [Brookfield 1987], [Garrison 1991] and empirical observations. To preserve the practical value of these taxonomies, we have tried to keep them reasonably simple and intuitive.

So far, the transcripts of four educational computer conferences (more conference transcripts to follow) have been analyzed using this approach and the developed scheme of categories. The emergent distributional structures of categorized cognitive acts and interactive moves performed by the learning groups under examination have been interpreted in light of the learning activities assigned by instructors (such as read and discuss, write a collective summary of the discussion, integrate information on the subject from external sources, etc.)

We argue that these distributional structures can be used to evaluate the group's performance and the educational success of the conference. They can be compared across conferences and related to chosen parameters of the learning situation. Also, the distributional structure of cognitive activity and interaction performed by indidvidual group members can be used to identify roles played by group members at the cognitive and the interactive plane and to evaluate their contribution to the outcomes of the collective learning experience.

Conclusion

As our project is still in its exploratory stage, we feel it would be premature to draw conclusions regarding the relationships between group interactive styles and cognitive activities. However, on the basis of the limited evidence collected so far, it can be hypothesized that groups demonstrating higher degree of interactivity (characterized by deeper involvement with other members' contributions such as support, challenge, partial disagreement, negotiation) and some degree of personal exposure (revealing personal feelings, providing personal information) tend to engage in more complex and more critical cognitive activity (characterized by analyzing problems, questioning positions expressed by others or encountered in the literature, taking new perspective to problems, etc.). We plan to explore this relationships in more depth as we gain access to more online educational conference transcripts.

We also believe that the approach we are suggesting in this paper can be brought to bear on the evaluation of online conferences for the practical purposes of instruction and technology assessment. Indisputably, the particular set of categories that is proposed here cannot be perceived as universally applicable across university disciplines and instructional goals. The idea that is generalizable across different contexts is to focus analysis and evaluation of online conferences on their cognitive and interactive dimensions developing a set of categories for each of these dimensions in accordance with the specific character of the instructional goals. Furthermore, the described analytical procedure, if found useful by instructors, could provide the basis for developing a software tool facilitating this kind of analysis.

In another vein, examining in detail what exactly students do discursively when they think critically and collaborate could provide instructors and online conference designers with helpful clues as to how to perceive and organize the online conference as a complex activity system, constituted of institutional rules and cultural norms, instructional goals, prescribed learning activities, literary sources, technological hardware and software, etc. One direction to explore is how to set the electronic "stage" so that its arrangement prompts and facilitates a particular (pedagogically desirable) kind of cognitive acts and interactive moves.

After 400 Multimedia Projects...

William G. W. Barnes
Choate Rosemary Hall, Wallingford, CT 06492 USA; wbarnes@Choate.edu

Abstract: The success of multimedia authoring projects produced by high school students is contingent on organization of the learning environment. Teachers must plan to model software, provide overviews of the project, produce template files, and supply handouts that describe all of the details to which students must attend. The storage of digital files organized into folders on cartridge drives simplifies the construction of multimedia projects. As the teacher's role shifts during this type of process-oriented work to that of a resource person, there is an inadequate of time to attend to these details once the projects begin.

Introduction

Limited access to computer facilities for an entire class is a problem requiring good organization for a unit of instruction resulting in multimedia projects [Mehan 1985]. Therefore, teachers must give adequate preparation to teaching students how to organize a project with an eye to the specific constraints impinging on the completion of work [ACOT 1991]. Throughout this paper, I am using two perspectives, the first being multimedia authoring flourishes under cooperative learning. This type of grouping fosters new understandings derived from student discussions, negotiation of meaning, reflection, and creation of mental models that emerge from conferences [Bracey 1991]. The second perspective is that authoring multimedia projects allow students to structure their ideas coherently for a large audience. With cooperative learning, a teacher moves into a new role guiding students as a resource person [Vygotsky 1978]. However, the advantages of cooperative learning, multimedia production, and this new role of teachers can only be safely attained by giving extensive care to classroom organization and management before multimedia authoring begins.

Planning Logistics for Project Completion

The complexity of managing multimedia projects requires a teacher to attend to many small organizational details in advance of launching a unit of instruction--not in the middle of it. Otherwise more and more time will be taken up with minutia rather than being spent with students trying to get them to clarify, expand, and give proof of their ideas [Cohen 1992].

Specifically, it is incumbent on an instructor to provide:

1. organization of a daily schedule for the duration of a unit.
2. directions for storage of computer files on servers or cartridge drives.
3. viewings of earlier projects pointing out the problems that each group had to overcome.
4. handouts for managing the details of scanning images, recording sound files, and assembling multimedia documents.
5. demonstrations of specific software packages via a computer projection system while students follow the teacher's mouse movements.
6. templates for projects with the buttons for navigation already in place for movement in a linear and standard hypertext fashion.
7. demonstration and use of concept mapping software for use in creating an overview of the project content and designing flowcharts of work to be accomplished by each collaborative group.
8. overviews of cooperative learning and the division of labor that typically occurs within a group.
9. time for the group to meet during class and access to computer workstations after the school day.
10. guidelines to explain how to organize sounds, graphics, video, and multimedia files in nested folders.
11. checklists for accomplishing all of the steps of a multimedia authoring project.

The Teacher as Organizer of the Instructional Environment

The use of hypermedia projects by secondary students to report research findings requires a high level of organization on the part of the teacher. High schools, no matter how well endowed with hardware in computer labs, are unable to provide sufficient resources for more than a few classes to produce lengthy multimedia projects in a concentrated period of time. Thus, out of necessity, taut organization must follow. At one level, the scheduling of rooms, due dates, and other logistics requires planning that takes place in the month before the unit of instruction begins. The date for demonstrating the projects must also be set. As a note of caution, we have found that projects require more time than teachers had originally scheduled and, thus, some of these projects become works in progress [Riel 1994].

At a higher level of complexity and detail, the teacher must always organize the means for storing projects. Currently, faculty arrange individual network accounts with passwords for each student. They key limitation of these accounts is that multimedia projects tend to run in a halting manner over a network when video and sound files are stored on a server. The most efficient means for organizing all student project resources used in multimedia production is on removable cartridges. These media must be in ample supply at the school bookstore. Removable cartridges can display multimedia files directly; archiving media such as Zip drives are not fast enough to display projects without first copying the entire document to the hard drive of a workstation.

After teachers resolve the storage issues for multimedia projects, students must learn how to organize data inside of the storage site. In short, this step means each group must learn to use nested color coded folders for holding separate scanned images, sounds, video, text, and authoring program files for efficient organization.

The Outcomes of Good Organization

As soon as these structures are in place, the collaborative groups can organize the main ideas and supporting details using well defined concept maps and begin writing these elements into a conventional research paper. The next step involves editing down this work sharply before copying and pasting the text out of a word processing file into the templates of the multimedia authoring program. If the logistical planning of the teacher has gone well, the assorted scanned images, sound files, Quicktime movies, and multimedia files lie in the designated folders of each collaborative group. Here is where the organization pays off. Students quickly assemble their multimedia document by juxtaposing the text with all of the digital files found in the resource folders. Without this planning, a class will spend endless hours in the computer center improvising solutions to problems needlessly encountered.

Using Proximity Matrices to Identify Predominant Patterns of Navigation Through Hypermedia Knowledge Spaces

Robert E. Beasley, Ph.D.
Computer Information Systems Program
Union College, USA
rbeasley@unionky.edu

Abstract:

In order to understand exactly how learners navigate through a given hypermedia application, it is necessary to observe their movements as they progress through and interact with it. By capturing and analyzing hypermedia navigation data, researchers and developers can gain insight into what types of learners navigate in what kinds of ways, better understand how learners go about developing knowledge in a particular domain, gather useful information for formative evaluation, accumulate data regarding the usage patterns of publicly displayed hypermedia presentations, provide learners with on-the-fly advice about how paths taken previously may bear on future choices or outcomes, determine why one path in a hypermedia application is typically chosen over another, and so on. The purpose of this article is to provide researchers and developers with a practical and effective approach to analyzing the paths learners take when progressing through a hypermedia application.

Introduction

The advent of the hypermedia application as a major means of delivering instruction in both educational and training environments has provided instructional designers with the ability to produce instructional materials that can be accessed in many different ways. This implies that two learners with the same learning objectives may navigate through the same hypermedia application in two completely different manners. This is due to the fact that learners typically bring to a given learning session different levels of interest in the topic, different world experiences, different informational needs, different levels of motivation, different problem-solving strategies, and so on, thus influencing how they navigate through the hypermedia environment [Canter, Rivers, & Storrs 1985; Jonassen 1988].

In order to understand exactly how learners navigate through a given hypermedia application, it is necessary to observe their movements as they progress through and interact with it. This is best accomplished by employing automated data collection scripts running in the background of the application itself. The benefits of using such scripts is that they can capture and store a learner's navigational choices both accurately and unobtrusively, thus improving the validity of the investigation [Qiu 1994].

Capturing and analyzing hypermedia navigation data is of interest for a number of reasons. [Beasley 1992] points out that data of this sort can be used to help us gain insight into what types of learners navigate in what kinds of ways and to better understand how learners go about developing knowledge in a particular domain. [Schwier & Misanchuk 1993] state that capturing and analyzing navigation data can provide useful information during formative evaluation, provide information for use in basic research, provide information regarding the usage patterns of publicly displayed hypermedia presentations, and provide learners with on-the-fly advice about how paths taken previously may bear on future choices or outcomes. Finally, [Orey & Nelson 1994] assert that data of this type can be used to help us understand why one path in a hypermedia application is typically chosen over another path, and how the choice of one path affects the choice of subsequent paths.

[Qiu 1994] argues that the actual paths followed by learners when navigating through a hypermedia application is a topic that has been rarely investigated and needs further study. This may be at least partly due to a lack of effective tools available that can be employ to analyze such data. The purpose of this article is to provide the researcher with both a practical and an effective approach to analyzing the paths learners take when progressing through a hypermedia application. This approach was developed for a recent investigation in which predominant patterns of navigation were identified for learners attempting to acquire knowledge from a hierarchically organized hypermedia application [Beasley & Waugh 1997]. A more complete description of this approach can be found in the CD-ROM version of this article [Beasley 1997].

Method

The method described in this article consists of six discrete steps: Data collection, data classification, proximity matrix development, navigation pattern derivation, link traversal significance determination, and visual representation.

Data Collection

For the [Beasley & Waugh 1997] study, each learner's navigation data was collected and stored in a text file by data collection scripts similar to those described in [Beasley 1992]. The data were collected in this manner because, again, they could be captured accurately and unobtrusively, thus improving the validity of the study. Upon starting the hypermedia lesson, each learner was prompted by the application to enter his or her initials and the last four digits of his or her social security number (e.g., reb5295). This participant code was used to guarantee anonymity in the study and at the same time allowed the researchers to keep each learner's data set together in a text file of that name (e.g., reb5295.txt). Each recorded entry in this file consisted of the code of the node moved to (e.g., 11, 22, 45), its title (included to aid any visual inspections of the data), and the amount of time spent on the node.

Data Classification

After the navigation data were collected and stored, the data in the Macintosh text files were converted to DOS text files and then imported into a Microsoft FoxPro 2.5b for Windows relational database table. A computer program was then developed to classify all node visits for each learner as either an initial visit or a review visit. An initial visit was defined as the first time a learner visited a given node, while a review visit was defined as any time a learner returned to a given node after visiting it initially. Classifying node visits in this manner permitted the researchers to track how the learners covered the nodes in the application the first time through it as well as how they covered them during review. It was hypothesized that these two phases of the learner's study session would produce markedly different patterns of navigation and should thus be segregated.

Proximity Matrix Development

Once all learner navigation data were imported into the relational database table, two proximity matrices were developed--one for the initial phase of the learners' study sessions and one for the review phase. Since there were 40 nodes in the lesson, each proximity matrix consisted of 40 columns and 40 rows. Each column-row intersection represented a potential link from one node to another. Thus, there were m(m - 1), or 40(39) = 1560, potential links between the nodes in the application, where m = 40 nodes. A computer program was then developed which incremented the corresponding row-column intersection by one, each time a given node-to-node link was traversed. After all navigation data were analyzed, the frequencies of individual link traversals were available in the two proximity matrices.

Navigation Pattern Derivation

After the proximity matrices were developed, predominant patterns of navigation through the hypermedia application were derived. This task was accomplished by systematically comparing the moves emanating from each node in the system. In the [Beasley & Waugh 1997] study, for example, there were four nodes (i.e., node 21, node 22, node 23, and node 24) to which a learner could move from node 11. A computer program was developed that determined which of the four possible links (i.e., node 11 to node 21, node 11 to node 22, node 11 to node 23, or node 11 to node 24) was traversed most frequently. After determining the most frequently taken link from node 11, the program moved across that link and began the process again until all the links were analyzed or the path in the proximity matrix was terminated. The algorithm used in this analysis does not allow a return visit to a node that has already been analyzed.

Link Traversal Significance Determination

Once predominant patterns of navigation were derived, each node-to-node link traversal was analyzed to determine if the proportion of traversals across that link was significantly larger than any non-predominant link traversals emanating from the same node. To do this, the proportion of each link traversal emanating from a given node was determined by dividing the number of traversals moving away from the current node by the number of visits to the current node. For example, the learners using the system moved from node 3f to node 24 thirty-three times and node 3f was visited a total of fifty-nine times. Thus, the proportion of moves from node 3f to 24 was 33/59 or 56 percent. Notice that this technique addresses the problem of what value to use in the denominator of such a proportion [Schwier & Misanchuk 1990]. Next, the statistical significance of this proportion was tested. A z-test was used to test the equality of two proportions, and that the proportions compared were those of the most frequently traversed link from a given node and those of the second most frequently traversed link from that same node.

Visual Representation

After each predominant node-to-node link traversal was analyzed to determine its statistical significance, a visual representation of these links was created. This was done to give the researchers a clearer understanding of the predominant patterns of navigation taken through the hypermedia application.

Abstract

In this work we report, from a piagetian logical-operatory point of view, some important concepts for the operatory analysis of the interaction processes between subjects and cooperative computational environments. We introduce construct three models which involve aspects of the user and/or programmer subject representation activity (like the mental image of the interaction process), as well as the relationships that can be realized among the subjects and the computational environment. We sketch in a preliminary way the intended use of the models.

Keywords: Computer Supported Cooperative Work (CSCW), Cooperative Environments, Operatory Analysis, Collective Representation.

The aim of this study is to investigate, from a piagetian operatory-logic point of view, different computational environments that allow the construction of a "*collective knowledge*". For that, it is necessary to understand some basic concepts of this theory which explain the subject's representative activity in an individual and collective level as well as the different elements that, in our interpretation, are involved in the cooperative interaction between subjects and the computational environments (elements like: the mental image of the interaction process, their computational representation in a individual/collective plan, etc). We use these concepts to construct and study some models of interaction processes in order to characterize the operations that are performed both by the programs and the subjects which are working together in a group.

To understand, from a logical operatory viewpoint, the interactions between the subjects and the cooperative computational environment, it is necessary not only to model the subjects cognitive and action structures in terms of operation structures, but also to model the computational cooperative environment in the same terms. Piaget's operatory logic was developed to model cognitive and action structures of subjects in problem-solving situations. But, to our knowledge, no suitable account has been given, in logical-operatory terms, of the behavior of computational environments.

Without such an account, modeling the interaction process between subjects and computational environments requires dealing with two fundamentally different languages: the logical-operatory language of Piaget's psychology and epistemology, and the language of theoretical computer science, where the semantics of computer systems are analyzed and explained. This language is very close to that of the so-called information processing psychology, which on its turn is quite distant from the language of Piaget's theory.

To fill the gap between those two different viewpoints, we propose to develop models of computer systems using the language of Piaget's operatory logic. This should be directly relevant to the piagetian study of human behavior in cooperative computational environments, since they should allow the description of user-computer interactions in the same logical-operatory language.

We've started the development of such models by analyzing in logical-operatory terms simple computer applications frequently used in educational environments, such as the graphical editor Paintbrush for Windows, the WinLogo programming environment, and the text editor Word 6.0, among others.

In such preliminary studies we explained in logical and infralogical terms both the behavior of subjects and computational environments, as well as their interactions. Such studies concerned non-cooperative situations, involving a single user and a single computer, and although they are the basis for the study of cooperative environments that we are starting to report here, they can not be directly applied to such cooperative environments, because of the additional involvement brought in by the presence of the interaction processes among the diverse subjects in such environments.

To organize the extension of our previous results concerning non-cooperative environments to the cooperative ones we intend to study some base models are necessary, which should be used to organize the logical-operatory analysis, allowing the definition of concepts such as organizational roles, organizational structures, and organizational processes [Costa 95], in which the piagetian logical-operatory concepts we used before can acquire the multi-subject dimensions needed for our current task. This study introduces three such base models, making explicit roles, structures and processes present in the use of cooperative computational environments, so that the definition of the logical-operatory structures needed for the analysis of such use can now proceed adequately.

The first type of interaction model is the simplest one. It concerns a centralized tool that is used in a cooperative form by several users. In this model, the users do their collective representation of the mental image through the language supported by the system in question. In the second model the computational tool is distributed, that is, each subject can access the system. Through the language tool they represent their mental image in a common collective form. It can be handled by the subjects in a direct or indirect way, using the system functions. The last model is a distributed tool, where each subject interact through an unique language supported by the environment, or, in a general case, through the self language of each other, representing their mental image in the computer. First in an individual form and then after to a cooperative form which reflects these "individuals representations". That is, we can observe as many representations as the number of subjects that are part of the environment.

This paper is a summary of a part of a Ph.D. work that the first author is undertaking [Behar and Costa 96a], [Behar and Costa 96b], [Behar and Costa 96c] and [Behar and Costa 97] in order to focus on the analysis of the different elements that are involved in a cooperative computational environment. With this purpose, we constructed some interaction models that can be used to help organize the development of a logical-operatory method for analyzing in detail the operations that can be executed by subjects participating in a group, interacting with each other through a cooperative computational tool.

We're going to base on the interaction models that we described in the full paper [Behar and Costa 97] the construction of an operatory analysis method in a collective level in the same way that we did in an individual plane.

Jump-Starting the Use of Technology in the Humanities Classroom

Dr. Alfred Benney
Fairfield University
Fairfield, CT 06430-5195
Benney@Fair1.Fairfield.edu

Abstract: This paper presents a unique method of encouraging faculty at a small liberal arts university to develop multimedia learning strategies. Our model is based on the premise that faculty are best equipped to teach and mentor one another. At Fairfield University, an interesting experiment begun four years ago, involving eight faculty from a variety of liberal arts disciplines has grown to a group of over forty active faculty from nearly every university discipline. These forty-plus educators are using computers in the classroom in ways as simple as electronic blackboards to ways as sophisticated as digital video. This paper analyzes the growth of this project and explores some of the factors that have contributed to its success.

I The Problem

Television has been with us for more than fifty years, and has yet to find its useful place in education. "Higher education spent billions of dollars on computer equipment during the 1980's. [But]. . .current studies indicate that the use of computers for instructional purposes has not yet hit the mainstream of university education." Despite the enthusiastic promotion of all sorts of technology for business, communication and entertainment, educators are only beginning to use technology in the classroom. Why is this so?

Researchers have explored such factors as expense, faculty incentives and the technical orientation of various disciplines in an effort to explain this reluctance of faculty to use technology in teaching. In humanities education the lack of creative applications of technology is especially obvious. But, does it have to be this way?

II Growth

In the summer of 1993, eight faculty at Fairfield University began informal discussions regarding educational applications of technology and the development of resources and projects for the use of technology in the University's classrooms. The group's organizers met with the university's vice-president for administration and outlined a proposal for the development of resources to support this initiative. They were encouraged to work with University Development to explore possible avenues of funding, and this cooperative effort led to a grant from the Booth-Ferris Foundation to create two MultiMedia classrooms and two portable classroom/development workstations as well as money for faculty workstations and training.

The University also funded from a variety of sources more than sixteen high-end workstations capable of developing several different kinds of MultiMedia projects, and the costs of a color scanner, a CD-Rom burner, sound boards, digital video boards and software needed to create courseware. Finally, a high-speed fiber-optic network made it possible for some of the group to be networked on a LAN, facilitating the exchange of large image files, digital video and training programs as well as an easy access to this information from several classrooms. By the end of that academic year, there were more than twenty faculty involved in this program.

The secret of this success may actually be attributed to the informality of its operation and the guidelines it has adopted in order to reach a clearly articulated set of goals. All members agree that the central focus is collaboration and a willingness to be generous in sharing one's expertise (no matter what the level) with colleagues. The Faculty Initiative Group (or FIG) adopted the following guidelines/principles for participation:

1) The objective of FIG is to take MultiMedia into the classroom in support of teaching/learning;
2) To further this objective, we recognize the need for faculty to learn the technology and its

applications, and to develop a competency that would reduce our need for technical support;

3) We therefore agree

  a) that each of us will develop a multimedia project that we will take into the classroom to enhance our teaching;

  b) that each of us will develop a particular specialty (or set of specialties) which we will be willing to make available to our colleagues if and when they need support;

  c) and that we will dedicate ourselves to collaboration and support of our colleagues in developing and sharing the application of multimedia resources, models, programs, classes and techniques.

4) The purpose of this initiative is to develop adequate resources for the use of MultiMedia in teaching Fairfield University students

III Discoveries

It became clear from the beginning that there were factors working against this time-consuming enterprise. For example, it is very difficult for young faculty to get involved simply because there is little or no value attached to this work for tenure or promotion. The academy is still suspicious of technology -- will it take my place? -- it is used to "babysit" a class! -- it requires no scholarship to create or use.

On the other hand, Faculty are often reluctant to work with non-faculty media experts for a variety of reasons:

a) Traditional attitude -- the classroom is my domain;

b) Courseware is very specific to discipline and class;

c) Professors are the content experts, but at the University level, they are also the presentation experts because of the complexity of the material/ideas;

d) Faculty experience often is that media experts seem not to understand the real complexities of the educational process -- that it is more than the delivery of ideas

e) Media experts often "sell" a particular style that does not suit the classroom techniques of the professor.

At a small university, financial restrictions often prohibit the development of technological teaching devices by professional experts. But our experience at Fairfield suggests an effective approach: that a self-selected group of faculty members from different specializations, when properly supported, can develop sophisticated teaching technologies if they are brought together in a congenial and cooperative fashion.

IV Findings

One of the major concerns of the group has been to question where/how the educator fits into the multimedia paradigm. Are we "engineers" running the train? Are we "objective scientists" experimenting with reality? Are we "innocent bystanders?" Or perhaps are we part of the experiment ourselves?

Communication is important for collaboration. Members of FIG meet on a regular basis every two or three weeks (usually over lunch) to discuss current projects, future plans, policy issues and needs. At these meetings they develop ideas and discover multidisciplinary connections as well as discuss the pedagogical issues surrounding student learning and new technology.

Communication does not take place simply because it is supported; communication takes place when faculty members perceive it as a value because it contributes directly to the teaching process. This cross-disciplinary dialogue encourages the teacher and enriches the program much to the benefit of the student. Thanks to this dialogue, the teacher cannot be distinguished from other learners and in fact finds him/herself in what can only be described as a "situated learning" environment. The experimenter is part of his/her experiment.

In addition to these meetings, faculty gather together for "FigDemo Days" at which we share ideas and some of the group present their current projects. We invite other segments of the university community to come to

BEST COPY AVAILABLE

these presentations to "look over our shoulders" and to participate in the ensuing discussion. This leads to a greater spirit of cooperation within the community, gives ownership to more people and ensures a greater chance for success because more people want it to succeed and see themselves as involved in the primary purpose of the university - - to educate the students!

V The Present Outcome

As we look to the next academic year, two critical factors stare back at us: first, the fiber-optic network has raised the hopes of the university community for easy communication and access for all to the information superhighway. Commitment to digital imaging and to faculty-authored courseware requires an easy electronic path to the classroom. Just as an adequate workstation makes the use of multimedia possible, so an adequate network makes the transportation of multimedia to the classroom possible.

The second "critical factor" is the need for training beyond the basics which includes not only computer literacy and advanced training in such authoring tools as ToolBook or Compel, but ethical behavior and on-line etiquette as well. We note that the culture of the university is being changed by this technology and so it is an issue for the entire community, faculty, staff, administration and students.

Finally, it is imperative to keep in mind that we are educators and that the focus of our activities must be the student. As we add the complexity of electronic interactivity to our repertoire of educational strategies, it becomes easier to focus on the process rather than the content of education. Communication does not take place simply because it's possible; communication takes place when people perceive it as a value because there is something about which they need to communicate.

The Hyperlanguage Project: A Work-in-Progress Report

Gunnar Bergh — David Mighetto
Department of English, Göteborg University, Sweden
bergh@eng.gu.se — mighetto@rom.gu.se

Abstract:
The main aim of *The Hyperlanguage Project* is to try to make use of some modern network (WWW) resources in today's academic teaching. Having a great potential in the fields of learner autonomy, individualization and internationalization, this idea is now being realized in the Department of English, Göteborg University through the development of an interactive on-line system for foreign language learning. The system consists of a local network platform which is based on the WebSTAR/West server software. It is designed to house a couple of IT-adapted courses with matching self-practice packages, where the course material has ample connection to various data, tools or other functions available on the Internet. The target teaching/learning units are two proficiency-related subcourses for first-term students of English – contrastive grammar and written proficiency.

1. Introduction

In the project to be sketched here, we try to take on some of the noted problems of undergraduate education in Sweden by making use of the pedagogical potential of the virtual university. The main impetus for venturing this is our realization that modern IT-technique is equipped with great educational possibilities which makes it likely to yield good results in terms of key notions such as the following:

(a) problem-oriented learning which promotes activity and creativity
(b) individualized learning with regard to pace and content
(c) stimulating setting which arouses curiosity
(d) knowledge which is both world-oriented and fresh
(e) intensified contacts between students and the external world
(f) transition of teacher functions from teacher/lecturer to mentor/supervisor

For these reasons, we have launched a two-year project – *The Hyperlanguage Project* – in the English department at Göteborg university which has the goal of developing and testing an interactive on-line system for foreign language learning.[1] Our work aims specifically at two proficiency-related subcourses for first-term students of English – contrastive grammar and written proficiency – where the intention is to compare in scientific manner the effects of IT-based learning with its traditional counterpart.

2. Build-up

The technical part of the system is realized through the implementation of a local network platform which is based on the WebSTAR/West server software. It is designed to house a couple of IT-adapted courses with matching self-practice packages, where the course material has ample connection to various data, tools or other functions available on the Internet.

Among the resources offered, databases and related information sources predominate. Thus, corpora of various kinds provide authentic examples of current grammatical patterns and idioms – sometimes based exclusively on language samples from the 1990s. Electronic dictionaries come in useful with regard to various aspects of lexical usage: their main function is to provide rapid and up-to-date information about current terminology, an effect which is often difficult to achieve with traditional dictionaries because of their publication lags and inherent limitation of search possibilities. Moreover, there are connections to a set of automatic language tools which may be of service in the different phases of language work, primarily in the description of language structure but also in the proofreading and editing of texts in general. These functions are performed by sophisticated parsers and checkers, which tend to facilitate much of the individual work with grammar, spelling, lexical choice, etc., thereby paving the way for further student autonomy. Finally, the resource collection contains a handful of teach-yourself courses and a rich collection of general, encyclopedic databases.

---

[1] Thanks are due to the Arts Faculty, Göteborg University and the Swedish Ministry of Education (DUKOM) for generous sponsoring of the project.

The self-practice packages, in their turn, consist of a collection of support material for the IT-adapted courses which resemble conventional CALL modules, except that they are network-based and provide automatic feedback facilities. They find their place in the handling of any individual language problems which may come to the fore in the students' regular course work, specifically such showing a tendency to represent idiosyncratic gaps rather than general trends in their underlying language competence.

3. Testing

With the basic build-up of the system approaching completion, we are currently entering the second phase of the project work – the testing of it. This phase will begin with a spell of informal pilot testing during which possible technical and pedagogical problems are sorted out, and will then be extended to a regular running of the selected courses in the curriculum for a period of (at least) two terms. The following matrix gives a rough outline of the pedagogical design of the project:

Contrastive grammar	Written proficiency
(1) IT-learning (test group: 10-15 stud.)	(2) IT-learning (test group: 10-15 stud.)
(3) traditional teaching (control group: 10-15 stud.)	(4) traditional teaching (control group: 10-15 stud.)

Apart from the possibility of making controlled comparisons between IT-learning and its traditional counterpart, this paradigm has the advantage that no departure from existing course plans is necessary. When testing the system, we intend, generally speaking, to put in a great deal of effort to balance out as many variables as possible. In this way, the combination of method and tool in the learning process is likely to be isolated as the main dependent variable, which poses as a guarantee for proper experimental conditions in the comprehensive evaluation of the results which will be carried out.

Benchmarking Decision-Making for Distance Education at U.S. Colleges and Universities

Thomas A. Birk, Ph.D., Visions Inc., USA, tbirk@visions-edtech.com
William C. Coscarelli, Ph.D., Southern Illinois University Carbondale, USA, 71052.3501@compuserve.com

Administrators at conventional four-year colleges and universities are besieged with increasing costs and competition, as well as declining or degrading resources. One of the more popular solutions has been to increase institutional efforts in the area of distance education. Popular in that it has gained political favor, and--under the right circumstances--can be cost-effective and efficient. Additionally, the research is clear, the learning outcomes of distance education courses and programs can be as good as, sometimes better than, conventional face-to-face instruction. The number of students now enrolled in distance education courses at the post-secondary level is at an all-time high [Moore 1995].

What seems to be missing in the euphoric rush to create distance education programs at conventional four-year colleges and universities is a regard for whether or not, under a given set of circumstances, distance education is the right answer, and why. Just as any other "magic bullet" that has been advanced in education over the past several decades, distance education has its strengths and limitations. It is not, nor is any one answer, ever the panacea to all of the issues confronting today's college administrator.

While research in distance education is relatively new [Holmberg 1987a], there has been a tendency to focus on media comparison studies and the role of the learner in distance education (e.g. [Harris 1995]; [Kember 1989]; [Wilkes & Burnham 1991]; [Whittington 1987]), with little work being done in the area of decision-making [Schlosser & Anderson 1994]. However, the research that has examined distance education planning and decision-making tends to proffer the warning that there tends to be an emphasis on distance education delivery systems and little, if any, attention to planning activities early in an intervention ([Chander 1991]; [Hayduk 1994]; [Rumble 1986]; [Verduin & Clark 1991]). [Holmberg 1987b] encapsulates this concern when he states that "all too often, however, those charged with setting up a distance education system are not given the choice to recommend against it."

For this study, distance education was said to exist when the learner and the instructor are separated, a medium or media of communication are employed and an educational institution is involved. The method, including the means by which benchmarking partners were selected, was developed primarily from the work of [Camp 1989] and [Spendolini 1992], and included four primary stages: determining what to benchmark, selecting the benchmarking partners, determining data collection procedures and collecting the data, and data analysis.

Using the rubric of benchmarking for best practices for the essential methodological structure, the following are the results from each stage. It was determined that the focus of the study would be to benchmark the decision-making strategies--as used by outstanding four-year colleges and universities in the United States that offer at least some courses or programs via distance education--which determine whether a program or course should be offered by means of distance education. Three institutions that met the definition of the above population were selected. Benchmarking partners for this study were: the University of Nebraska-Lincoln, The Pennsylvania State University and the University of Kentucky. Data were collected from a review of the literature, distance learning consultants and professional organizations, site visitations, telephone interviews, the gathering and inspection of physical artifacts and personal interviews at each institution. The study was conducted between January and September of 1996.

There were several common salient issues that emerged from the benchmarked institutions in terms of their approaches to decision-making in distance education. Given the frequency and global nature of emergence of these issues or themes across the institutions studied, it seems appropriate to identify them collectively as a "best practices" method. These issues were: the importance of needs assessment; involvement of key personnel in the decision-making process; the assurance of academic quality and instructional validity of courses or programs offered at a distance; the certainty and quality of support mechanisms for the unique needs of distance students; and a commitment on the part of the institution to distance education.

Needs Assessment

Each institution studied noted the necessity to conduct proper needs assessment as a means of determining demand for current course and program offerings as well as exploring possible new courses or programs. It was also seen as a fiscally sound approach to developing and improving the distance curriculum at these institutions.

Distance education is often regarded as a income-generating component at a public university, and is likely to be self-sustaining. Given this fact, and the expense of distance education, particularly with the emergence of new, and expensive, technologies, proper needs assessment is critical to avoid costly miscalculations of whether a course or program will be successful.

Involvement of Key Personnel

At each of the three benchmarked institutions, members of the academic department or college were always involved in the decision as to whether or not to offer a course or program at a distance. At each institution, there was a service unit responsible specifically for distance education. At all of the institutions, both of these entities were involved in implementation, and at two of the three, both were always involved in the initial decision-making.

Academic Quality

Each institution classified the academic department or college decision-makers as the most important in the decision-making process. Each school involves these individuals in all phases of decision-making, design and implementation, and each alluded to the fact that having representation from the distance arena on academic policy boards or committees, or having a member of the distance organization with the rank of dean was seen as lending importance and academic credibility to the practice of distance education on their respective campuses. Further, each institution only allows personnel with faculty status to teach courses at a distance.

Administrators at each of the institutions studied revealed that a perceived strength in their decision-making process was careful attention to the instructional design of the courses they offered at a distance. Among the design issues that emerged as the most critical were appropriate selection of instructional delivery systems (specifically, choosing those that were responsive to the course content and the unique needs of the individual distance learner), feedback strategies, secure and equitable evaluation methods and the establishment of strong communication links between the instructor and the learner.

Support Systems for Distant Learners

Students who take courses or are involved in programs at a distance have special needs. Typically they are taking a course at a distance because they are time- or place-bound, and do not have the opportunity to take classes at a central campus location. Students should be able to conduct the administrative tasks at a distance as well as take courses. At the institutions studied, learners are able to register for classes and buy books either on-line or over the phone. Communication with advisors, instructors and classmates is often handled by phone, FAX, electronic mail or a combination of these technologies. Especially for graduate students, access to research is a critical issue. By providing access to the university's library holdings on line or through direct contact with library and media personnel at other institutions or communities closer to the distant learner, these institutions are able to provide access to quality research materials.

Institutional Commitment

Commitment on the part of the institution to provide support as well as resources to distance education instructors, administrators and students is a crucial element to the success of distance education interventions. One way each of these institutions expressed commitment to the process of distance education is the fact that it is policy not to distinguish a course taken on campus from a course taken at a distance on the students' official transcripts. Another commonality of each of these institutions in their processes of decision-making is that it is tied to the university's mission. Finally, each institution developed an organizational structure to support distance education that included a service unit or agency with distance education as its central function. This central agency serves the institutions by centralizing distance education expertise in advisement, delivery and technology.

Conclusion

It is therefore recommended that the decision-making process as to whether or not to offer a course or program at a distance should initially include addressing these questions: How does the use of a particular distance education intervention impact the mission of the institution? Is the program or course being delivered via an appropriate distance education delivery system? Are there sufficient and appropriate resources available to address the unique needs of the distance learner? The answers to these questions should give the decision-maker or decision-makers an initial reading on whether a particular program or course should or should not be offered at a distance.

Abstract

Using benchmarking for best practices as the primary methodological structure for this study, the author investigated the decision-making practices relative to distance education at three universities in the United States: the University of Nebraska-Lincoln, The Pennsylvania State University and the University of Kentucky. When determining whether or not to offer a course or program at a distance, the aggregate data suggested a best practices approach to decision-making. Among the primary issues which emerged from the study were: the importance of needs assessment; involvement of key personnel in the decision-making process; the assurance of academic quality and instructional validity of courses or programs offered at a distance; the certainty and quality of support mechanisms for the unique needs of distance students; and a commitment on the part of the institution to distance education.

Fax: 418-656-2324

Abstract : In this paper, the author first summarizes the content of the television distance education course Computer hardware and software components (Organisation matérielle et logicielle de l'ordinateur). Then, she explains the story behing the development to make sure to be successful with this kind of teaching material. She concludes with observations concerning the dreamers and the doers.

1. Introduction

The Computer hardware and software components distance education course aims at giving a fundamental knowledge related to computer hardware. It is part of several undergraduate programs of the Computer science Department from Université Laval. The main goal of the course is to allow the students to understand how a computer with its various components works to be able to advise its clients or employer concerning the best configuration and to the most relevant peripherals for a particular computer use, to make the most of the computer capacities and of the computer programming activities and to be able to react quickly and properly when a computer breakdown happens. Several parts of computers are explained within specialized books and one is used as a mandatory one [Zanella and Ligier 1993]. However, as we observed that the students were able to explain those parts with their properties when taken separately but, were not able when they were confronted to "a particular computer use" such as a flight simulator or an automatic banking machine, etc., it was decided to use learning technologies. Thirteen television programs (documentaries) were added to present several "particular computer uses". The content of one television program is first summarized. Then, the story behind is summarized and finally comments on the life within the unstable domain of distance education are made.

2. The content of the third television program

Within the third unit written material [Zanelli and Ligier, 1993], students learn how fractional and floating-point numbers are represented within a computer and how it does calculation. The television program three entitled "Using the chips" was designed to give emphasis to the fact that hardware and software are two concepts that should not be dissociated. In the first part, a computer professional from the CGI Consulting Group gives the particulars of prototyping (First image at [Fig. 1]). Then, we are in Montréal IBM office with a computer professional who shows and explains all the hardware and software components of an automatic banking machine [Fig. 1]. The intent was to prepare the students to consider simultaneously the hardware and software problems when proposing a solution to their employers or clients.

3. The story behind

As tele-learning, distance education, etc, are fashionable, the administrative personnel of universities wants to compete so, asks for this kind of teaching and learning material. As there is no evidence (as example concerning the "best" way to teach an attitude (such as be cautious when advising a client or an employer), a concept (such as how some specific parts of a computer work), etc.) in regards to distance education so, what do you do to avoid a failure? You have to duplicate the way you are presenting a content to offer a variety of teaching and learning strategies.

Figure 1 : Three images coming from the television program three.

The "variations" for the Computer hardware and software components course are the following: 1- A mandatory book [Zanella and Ligier 1993] that presents the fundamental knowledge; 2- A course notebook [Marchand 1996] using other terms and examples to precise the fundamental; 3- A study guide [Boulet and Marchand 1996] that details what to do, how to do it, what are the learning objectives of each activity of a particular learning unit and why it is useful to learn that considering the workplace needs; 4- Thirteen television programs (documentaries) that are presented on cable television. They can also be seen at the library of the University. Any student can have a copy of them if she or he pays the fees of videocassettes; 5- Lot of exercises with their solutions in the written material; 6- Lot of exercises without their solutions that will be solved during special activities; 7- Electronic version of the learning and teaching materials; 8- Special activities that can be done in a classroom with the professor solving the exercises in front of the classroom in accordance with a precise schedule, or anytime via Internet either alone or with a small group of students linked to the professor, or on appointment at the professor office, or by solving them alone and sending the solutions either by mail, email, fax to the professor to have her or his comments on paper; 9- Graded exercises; 10- Two class exams that can be done either in the University, or in a remote site, or under the official supervision of someone that exercises a liberal profession; as it is not sure that every students have the exam done at the same time, several versions of each exam must be prepared; 11- Individual links with the professor to obtain help and additional explanations using either the phone (the professor has a page), the fax, an appointment at the professor office, the email or any combination of these.

4. Conclusion

Because telelearning, distance education, learning technologies, etc, are fashionable, everybody have an opinion, not always based on a factual experience (the "dreamers"). As the financial resources are cut, the administrative personnel of universities are inclined to listen to the dreamers instead of listening to the doers. The dreamers have the time to promote concepts such as virtual campus, virtual universities, etc. putting the emphasis on the save of money. Those dreamers diminish the extent of the work that must be done and do not even mention the actual effect on learners. They forgot to mention the fact that you do not produce a course one time forever. Each year, you have to make some adding. The doers must duplicate themselves to be successful. They have no energy left to be able to present the reality of thing to the administrative personnel.

Abstract: A project called Instructional Design for Collaborative Distance Learning is presented, which is part of the Network of Centers of Excellence on Telelearning in Canada. Its goal is to provide instructional designers with the appropriate principles and tools to design learning activities and environments for collaborative learning at a distance.

The potential of multimedia telecommunications opens the way to hybrid solutions of on-campus and distance learning systems. Designing such solutions is a challenge for designers who use an established Instructional Design (ID) methodology, as is the norm in workplace education and training. This project focuses on design issues for collaborative telelearning and its applications for the workplace. Given the status of the knowledge in this field, an empirical approach is used for developing an instructional design methodology for collaborative telelearning. With respect to different design questions, learning scenarios and environments are developed and field-tested that allow design principles to be elaborated.

Extending an instructional design methodology

Methods for developing the ID principles include methods for elaborating and implementing them in instructional methods and implementing and testing these methods in learning environments. The project has initially selected two instructional methods: business simulation and science laboratory. Aspects of each of these methods will be explored through an iterative process of prototype development and field-testing in the appropriate educational setting.

In the teaching of Business Administration, a business simulation has been in use for some years in the Strategic Planning curriculum, where teams worked in a laboratory, coached by a professor or assistant, who also conducts the important briefing and debriefing sessions. Students have access to a set of actions, with a given time frame to create and try out a business strategy for each of the five given periods. After each period, all files are compiled by the simulation engine, and results are given back to students for the next period. Briefing and debriefing as well as tutoring can happen at a distance and be supported by interactive tele-presentation software and multipoint videoconferencing. A Web-based called NetStrat has been developed, with teams interacting on the network in real-time, thus giving students a better sense of reality. Data collection tools have been prepared and used for a first field-testing, consisting of structured diaries, computer trace files, video recording, and semi-structured interviews. These tools will be refined for further field-testing, in order to allow interpretation of data from multiple and multimedia sources. (See Bourdeau & Winer, 1996).

The science laboratory is seen as central to science teaching by those who believe that it promotes positive attitudes toward science, scientific attitudes, scientific inquiry, conceptual development, and technical skills. As a learning environment and an instructional strategy, the science laboratory includes practical work within planned learning experiences taking place in a purposely assigned environment (Lazarowitz &

Tamir, 1994). The important aspect of a learning lab is the controlled nature of the actions and the environment which permits generalization by the students beyond the specific instance under study. The context of a collaborative science learning laboratory for distance education adds the challenge that the students are not in the same physical and temporal space as their teammates and their teacher. This creates a particular set of needs and constraints for the teaching and learning environment. The Centre Collégial de Formation à Distance (CCFD) is providing a Distance learning System for the implementation of a lab for learning science in a distance collaborative mode. Data collection tools will consist of structured questionnaires, and semi structured interviews.

Toward the modeling of Collaborative Telelearning

Collaborative telelearning events can happen in environments that can support them, i.e. that have: (a) the completeness of distance learning systems, (b) flexibility to support synchronous and asynchronous (3) interoperability, (4) robustness. Such an environment is under construction at Télé-université (Paquette et al., 1995). Generic ID processes are specified for multimedia teletraining, and collaborative telelearning is considered as a set of use cases in this modeling system.

Artificial intelligence in education has several techniques to offer collaborative distance learning. Three of these -- learner modeling, cognitive diagnosis and dynamic pedagogical decision-making -- are being investigated. Instructional planning, as defined by the application of artificial intelligence planning techniques in education, is aimed at providing dynamic pedagogical decision making. The planning and decision making is dynamic in nature due to the constant updating of a learner model as the learning situation unfolds. Although typically used for one-on-one tutoring for content selection, deciding how to deliver content, and provide motivation, it has recently been proposed that instructional planning is applicable in collaborative learning environments as well (Vassileva & Wasson, 1996). Cognitive and affective goals will be augmented with collaborative goals such as facilitate collaboration, suggest peers for effective collaboration, or address feedback to the collaborative team and instructional planning rules such as if the partners in the group are not collaborating, then give group feedback and encourage them to work together are being identified.

The challenge in this project is to build and validate instructional design knowledge for collaborative distance learning, describing how to specify interdependencies between actors, processes and tasks, how to orchestrate distributed cognitive activities, how to design instruction based on interdependencies and sharing. Collaborative telelearning has the potential to reduce a student's isolation in distance learning, and the limits will then be only the creativity of instructional designers in using networks as cognitive tools for supporting socially shared cognition, and in using technologies as instruments for change in education.

Abstract: At Spelman College, the Multimedia Mathematics Education Research Group (M^2ERG) is developing an interactive learning environment on Statistics by using goal-based scenarios as its theoretical framework. The theory was developed by researchers at the Institute for Learning Sciences (ILS) at Northwestern University. This project will have a CD-ROM as its final product, and the CD-ROM will be designed for both the Macintosh and PC platforms.

The vehicle for the learning process is the marketing of a product and the user will encounter various statistical methodologies in the process. Finally, the project is aimed at students who are enrolled in Mathematics for Liberal Arts courses as well as high school juniors and seniors.

INTRODUCTION

In June, 1990, thirty nine individuals representing universities, colleges, business, industry and consulting firms attended a conference at the University of Iowa which addressed the problems in statistical education. (Hogg., et. al. 1992). The participants came to the conclusion that a major overhaul was needed in order to take subject matter that is not a favorite of very many students, and make it an understandable and lively endeavor. The group stated several reasons for the undesirable condition of statistical education. Some of the reasons given are as follows: (1) statistics teaching is often stagnant, and statistics teachers resist change, (2) techniques are often taught in isolation, with inadequate motivation and with no connection to a philosophy that connect them to real events, and (3) there is also failure to use the wide variety of simulations, experiments and individual or group projects which can make statistics come alive while simultaneously enhancing student understanding.

GOAL-BASED SCENARIOS

The theoretical framework for our project is goal-based scenarios, a theory that was developed at the Institute for the Learning Sciences (ILS) at Northwestern University. The main thrust of a goal-based scenario is to use target skills in the form of a cover story and then define a mission or task that you want the user to accomplish. In our project, the target skills are statistical in nature, the cover story is the marketing of a new breakfast cereal, and the mission is to successfully sell the product in the marketplace. Another way of viewing the above is that the user will be learning by doing.

INSTRUCTIONAL DESIGN

The instructional design phase of our project has been an integral part of the entire project. Our approach is to have a brainstorming session on how we would like to present a statistical technique and then lay it on the table for critical discussion. The process has been very fruitful because M^2ERG is a mixture of students and faculty. The students in our group have promulgated ideas from the perspective of the potential users of our CD-ROM. That is, they have come up with the product that we are marketing (breakfast cereal); potential animated characters that may be appealing to students; and they have rejected ideas that would be boring for teenage high school and college students. In this process, we decide how we would like for screens to look, and then we sit down at the computer and make the ideas come alive.

The main development tool for the project is Authorware 3.5. The components are graphics, text, animation, sound and video; and the storyline is the marketing of a new breakfast cereal. The user of the CD-ROM will be hired as a marketing professional and his or her job will be to promote this product in the marketplace. In the process of promotion, the student must use statistical techniques to make decisions relative to pricing, potential customer base, shelf space in supermarkets, and other facets of the marketing arena. The user will be awarded for a good performance, and criticized on failure to move the product. The idea is to put the statistics in a real world setting and show that decision making is a major use of statistics in the workplace.

TECHNICAL ISSUES

In any multimedia project, there are several technical issues that the developers must confront. A major technical issue for our group has been cross platform development. In essence, all of the group's work is via a power macintosh machine, but we have to be aware of the problems surrounding the use of our product on a windows-based machine. Thus, we have a technical consultant whose expertise is cross platform development and the preparation of files for use on multiple platforms.

CONCLUSION

Our goal is to have the CD-ROM completed by August, 1996 for both the windows and macintosh platforms. We will also write documentation to accompany the software. The next phase of the project is to pilot the CD-ROM with selected high schools and colleges and then evaluate the effectiveness of the instruction. We plan to commence this evaluation in the Spring of 1998.

Developing a Multimedia Template for Classroom Learning of History and Geography

Kevin Brady
and
Claude Toth,
Organizational Learning and Instructional Technology
College of Education, University of New Mexico, USA, 87131

The development of new multimedia technologies has stimulated considerable discussion and research into how they can be used for education. Some programs focus on using the computer as an instructor, while others use the computer to simulate experiments and experiences. Still other programs try to reinforce student learning by providing a variety of routes to the same information along with opportunities to explore the topic at greater depth.

The approach we are following advocates using the computer as a tool for student learning through doing. This is an approach exemplified by the Computer as Learning Partner project at Berkeley (Kirkpatrick 1995) and at the Institute for the Learning Sciences at Northwestern University.(Shank & Cleary 1994) In addition, we are developing our program using off-the-shelf software, an approach that has been investigated by the RAND Corporation. (McArthur et al 1994)

Our program is a template for learning history and geography. The interface is a topographic map of the state of New Mexico. The map serves as a gateway for files that contain historical and geographical information about places and regions within the state. These files can be developed and compiled by the students and then presented either locally or through the Internet. The files can contain text, maps, photo images, sound and video.

We developed the first version of the template using Adobe Photoshop and CorelDraw. We then assemble the program using Authorware. The photographs were digitized by Seattle Filmworks, and further rendered using Photoworks and Corel Photo-Paint. The topographic map was developed from satellite photographs by Ray Sterner at Johns Hopkins University.((http://fermi.jhuapl.edu/states/states.html) The textual material is based on standard reference works.

All of these programs are commercially available, widely used, and affordable for colleges and schools. We feel this is very important. Students should be exposed to the software they will encounter outside of school and, at the same time, the costs to the schools need to be kept at reasonable levels.

Using this template, students can learn history by doing the same things that historians do. They collect material relating to the past, organize it, assess its significance and present it. Once the project has begun, it can continue indefinitely. It can also be linked to other similar projects around the world. (Cole 1995) (http://www.stg.brown.edu/projects/WWII_Women/tocCS.html "What Did You Do In the War, Grandma?")

Direct learning by the students is accompanied by indirect learning. In collecting materials for the program, they discover the varieties of meaning in historical artifacts. They also confront the many interpretations that individuals develop concerning past events. They thus can begin to develop a deeper appreciation for the historians' task .(Rosenzweig 1995)

Additional learning develops about the computer and its programs. Students learn the programs by actually using them. They also confront the limitations of the computer as they attempt to use it for communication and presentation.

At the same time as the students are learning about history by creating these documents, they also learn about computers and computer programs by using them in the same fashion as they are used in the real world.(McArthur et al 1994)

Developing the materials for the original version of our program was relatively straightforward. The graphics and sound editing programs were fairly simple to use. However, once it became time to assemble the program we discovered that Authorware was not very friendly. In addition to difficulties in programming, we found that the Authorware version we were using was not well-adapted for straight presentations. (More recent versions of the program have resolved some of these difficulties.)

It was apparent that Authorware was not a program suitable for classroom use by teachers and students. It simply takes too long to master.

A second version of the program was developed using HTML as the mark-up language. This proved very successful and simple. We used a shareware program from the Internet to perform the basic mark-up. We created the map interface using another piece of shareware, MapEdit, which is free for educational institutions.

This process was very straightforward and inexpensive. We had to drop the use of video and sound files, simply because they took up so much memory space, were difficult to render (the video, especially) and because our current server doesn't allow for video loading at present. However, the final project fits on a floppy disk and is easily downloaded. Moreover, because of the nature of HTML, students and teachers can simply take ou program and insert their own material for ours, leaving the basic structure intact.

In developing this version of our project, the most difficult task was mastering the "tables" function of HTML. The tables function allows us to have some control of the positioning of elements on the screen. Now that we have created the base document, others can simply cut-and-paste from our program to create their own.

Finally, in the second version of this project, we gave more attention to questions of effective design.(Hoadley and Bell 1996) We wanted to create a template that would be easy to use, yet provide the user with an attractive appearance and easy access to navigational information about the rest of the program. In developing this version, we relied heavily upon the design guidelines developed by Yale University Medical School's Center for Advanced Instructional Materials. These materials are available over the internet at http://info.med.yale.edu/caim/stylemanual.

In conclusion, it appears to us that the internet and HTML based programming offer an ease and simplicity of production which other multimedia tools lack. The ability to find and "borrow" ideas and templates from a wide variety of sources is another benefit of web-based multimedia.

Our nest step in this project is to disseminate it to teachers and schools and begin assessing its effectiveness in a classroom setting.

Abstract: This paper outlines the development, methodology, and philosophy, of the PolyMath group's M3/Plexus project. Our goal is to use new technology, such as Java, to create a seamless learning environment appropriate for a fully collaborative virtual classroom, and for tele-learning and distance education methodologies. We propose to integrate the plethora of currently available resources and technologies in order to form an integrated computational environment which is flexible enough to accept future resources as they become available, simple enough to be used by non-experts, and accessible to more schools and colleges.

Introduction

Since the beginnings of mathematics education, there has always been a form of interactive learning and of interactive mathematics. Whether the teacher approached the student at her desk, or illustrated a concept on the blackboard, the student has always has the opportunity to ask questions and seek alternative answers. The answers have often been sought by a modification, by the student, of the information presented on a blackboard. This interaction with knowledge is crucial in learning, and forms a major part of the human relationship between student and teacher. As we move into this technological age where distance education and electronic textbooks become important means of education, we must ensure that we preserve this spirit of student/teacher interaction and student exploration.

We believe that distance education can be, and must be, more than a fancy electronic classroom. The power of the Internet, combined with an intelligent development and dissemination of sophisticated platforms can challenge the ways we currently teach and do mathematics. Students will be able to participate in their own learning and discovery processes, be guided into building problem-solving strategies, and given access to the same tools that a research level mathematician might use. One goal of the PolyMath group's M3/Plexus project is to provide an integrated yet broad spectrum of experimental and visual explorative tools which can make mathematics live and exciting for our students. And, because mathematics is the language of all the sciences, such platforms can be as valuable to a student of physics, biology or chemistry as they are to a student of mathematics.

Phase I

The first phase of the Multi-Modal Mathematics (M3/Plexus) project was the Organic Mathematics Project. {http://www.cecm.sfu.ca/projects/OMP/} This was an experimental investigation of the concept of activated mathematics, in which mathematical documents become "live" entities on the World Wide Web (WWW). They are connected to each other, to algorithms for live mathematical works, and to resources elsewhere on the Web. They contain hypertext links with a variety of media tools (audio, video, animation, text), advanced interactive mathematical tools, and an annotation tool which promotes communication and possible collaboration among mathematicians. Although this Project was primarily intended for research mathematicians, we were forced to reflect upon many of the issues involved in creating a seamless learning environment.

It became apparent that merely designing tools for exploration and manipulation was an insufficient approach to supporting a problem-solving environment in which the student is actually engaged in "doing" mathematics, i.e. asking their own questions.

We also discovered that a simple annotation system does not satisfy the need for the intuitive communication design required in a distance learning environment. It is not sufficient for students to be able to annotate and comment, they must be able to communicate in real-time using equations, pictures, and formulae. Nothing is more discouraging to a student than having someone try to explain math in words or having to interrupt their thought processes to wait for help. Moreover, the teacher must be able to follow the student's reasoning in order to effectively guide the student -- to transfer experience and intuition rather than answers.

This demand for flexible forms of data for the mathematical sciences presents enormous challenges. There are already sophisticated pieces of software that support this, yet they remain inaccessible to most schools and colleges, and they remain in isolation of other essential mathematical tools.

Goals

We would like to develop a set of strategies for linking these tools together -- to aggregate, activate and deliver mathematical resources in order to provide a coherent, engaging, flexible environment. We must cater to the huge gamut of different computational platforms, and mitigate the need for users to purchase expensive pieces of hardware or software. This is truly essential, for knowlege and education must be easily available to all, independent of ability to pay for excessively sophisticated resources. We must be careful that our technology does not foster the special education of only a rich elite of students who can afford specialized computing systems. Furthermore, It is essential that the teachers' and students' needs be driving the technology rather than having technology dictate which services or which resources are included. They must have the choice to incorporate tools at any stage within any system.

Our solution is to provide a sophisticated set of integration services, using Java and the latest distributed object technologies, that will allow us to assemble new and existing scientific educational tools into flexible educational systems. The services communicate with each other using PolyMath's Activated Scientific Knowledge through Universal Semantics} (AskUs) framework. AskUs allows for the exchange of syntactically semantically complicated information like mathematics between tools and over the network, and is designed to be implementable and useable through a wide range of networking technologies. The semantic information is exchanged via a flexible networking framework called PolyNet, which provides for encoding and decoding of the kind of relational data trees that are often used to represent mathematics, as well as the information describing the interaction between computational tools.

The PolyMath AskUs technologies allow advanced mathematical, and other scientific, tools to be distributed over many powerful computers, and for those tools to be controlled using clients, written in Java, that can be used by anybody with a current Web browser such as Netscape Communicator.

PolyNet and AskUs allow for many different environments to be created, rather than dictating a single approach to education and collaboration. It becomes up to the student or teacher to decide when or how they use different resources -- whether they choose to build a general environment or one specifically suited to individual needs. This allows the PolyMath group to construct educational solutions ranging from online educational textbooks to full collaborative environments for research-level communication between mathematical scientists.

Solutions

One example is the on-line textbook which is currently in development. It provides the student with the tools to develop a problem-solving strategy, explore databases of resources, and engage in both visual and computational discovery. A typical problem will offer the opportunity for the student to come to a more sophisticated understanding of new concepts and to apply this understanding in the problem solving procedure. The student can experiment with equations and formulae using software programs like Maple, interact with graphical displays in a familiar way and see the numerical results of their manipulations.

The PolyBook interface integrates different tools that a student could use in solving a problem. The tools themselves are interactive; the student can move the regions in the graph and the table at the bottom of the screen will change according to the configuration of the graph. Moreover, the student can use Maple to experiment with the findings in the table or on the graph. Should students want to explore a different facet of the problem -- they are free to call on another tool and continue to observe the interaction with the original tools.

The crux of the system is the flexibility of the tools which fosters a true spirit of participation, their interactivity, and their intuitive nature. The passage from one environment to another is natural and flexible. The student is guided by the framework (i.e. the tools initially available) yet free to explore the problems in many different ways.

Another example is the PolyMath online blackboard, a fully collaborative communication environment. This potentially provides a forum for student/student and student/teacher interaction, and thus for true collaborative learning, which is so crucial to successful distance learning.

A teacher can access the work in progress of a student, comment directly on both numerical and symbolic computations, provide guidance in the form of visual aids, be they illustrations or even sophisticated graphics, and respond immediately to the student's queries. The interface is completely natural in the same way that a blackboard is in the classroom with the added bonus that both teacher and student have access to powerful mathematical tools.

The student can make comments as he goes along letting the teacher know how he is progressing. The opportunity for the student to be able to communicate, to not feel isolated in the learning environment is central for effective participation. The essential tutorial component of humans educating humans is preserved.

In addition, the development of the problem, including comments, corrections, and hints, can be stored and easily retrieved. This captures the highly valuable and central creative process involved in "doing" mathematics, science, and engineering. The comments could be extremely useful to other students, and could even be used as hints to guide the work of an entire class.

Furthermore, new resources that are available on the web can be automatically integrated into this environment, so that a teacher might find an alternate way of representing a new concept for a particular student's needs, or students can call upon new tools which might help them experiment with a concept or problem. The systems provide a toolbox, from which students and teachers can build what they need.

The beauty of both these solutions is that the programs needed to create the environment sit on the network and provide the various services to the users. These services can be distributed across the network and do not have to sit on one machine. They can then be encapsulated inside an easy to use environment that avoids

Teachers needing to learn to install and use the system,
Schools, small colleges, and students having to buy the software,
Schools, small colleges, and students needing to buy high-end hardware to be able to run the software (aim: to run this stuff on low level, less than 500 dollars, hardware in the future).

Conclusion

We wish to build an integrated learning environment capable of being amenable to a variety of users. It should offer, at minimum, the following: A locally or remotely guided directed learning environment: Appropriate for K-12 and post-secondary learning. Utilizes a central master process controlling the path of clients through the subject material. An internet based research and exchange environment: Permits user to exchange, effortlessly author and integrate new and extant resources.

The idea is to distribute sophisticated computing resources throughout the world to anybody with "basic" network and computing access in a way that does not compromise functionality, and enhances education, communication, and collaboration. We want to ensure that the essential spirit of interaction and experimentation is maintained whether the learning is between students, between researchers, between a teacher and a student, or in a classroom situation. And finally, the distribution must not interfere with the preferred educational approach of any student or teacher. Technology that reduces human freedom in education should not be deployed. Education is more than static knowledge, and hence will always be more than an online textbook can deliver.

Much more is to be learned through initial trials of these environments in both the K-12 and undergraduate environments. We look forward to the imminent initiation of these trials, which in fact constitutes the next step in the M3/Plexus project.

Abstract

A CD ROM-based instructor resource kit that uses the storage and search capabilities of the CD ROM to provide instructors with easily accessible and reproducible classroom-based curriculum frameworks, lesson plans, and supporting instructor lectures and student activities. The project aimed at providing maximum functionality to the classroom trainer as well as to the self-directed learner by drawing the recent presentation and electronic publishing technologies while time staying within the technological constraints of the developing world. All materials are housed in an object-oriented database that provides a system for managing, searching, and browsing media elements including text, audio, 3-D and video. Visuals may be projected full-screen by launching the Powerpoint viewer. Visuals and all other text materials are captured as PDF files and may be viewed, searched, and printed using Acrobat.

The Problem

How to take twenty years of trainers' knowledge and experience comprising five weeks of classroom training on project management, distill it, and disseminate it easily, quickly, and cheaply to developing countries to get the biggest multiplier effect? Filling the knowledge gap is a central concern in international development. The need for learning resources in developing countries is great; but, in many countries, technology-assisted delivery is constrained by lack of hardware, software, and a teaching culture that is based on skills training in the classroom instruction.

The Solution

The technological equivalent of putting old wine in new bottles: *a CD ROM-based instructor* resource that uses the storage and search capabilities of the CD ROM to provide instructors with *easily accessible and reproducible* classroom-based curriculum frameworks, lesson plans, and supporting instructor lectures and student activities. Instructors can use the contents of the CD in three primary ways: as a source of inspiration for course development, as a source of hard-to-find student readings, activities, and lectures for enhancing existing courses, or as a "ready-made" course which they deliver as designed. Files can be downloaded and customized to meet local needs. All materials can be reproduced using a laser printer, so the CD ROM serves as a virtual printing press for instructors, an important function in developing countries where access to copying equipment is often limited. The Economic Development Institute (EDI) of the World Bank promotes economic growth in the developing world by sharing the World Bank's expertise through networks of government officials, universities and research institutes, regional development banks, and nongovernmental organizations. Part of EDI's mission is to prepare and disseminate high-quality learning materials worldwide.

The CD-ROM Resource Kit

Effective project management is essential to meeting time, cost, and quality objectives in the implementation of World Bank projects. The CD-ROM contains 12 modules of print-based training materials on managing project implementation. This electronic product is expected to help "wholesale" training by providing a standardized core of high-quality learning resources for students, trainers, and practitioners in developed and developing countries. It is based on a collection of printed materials used for classroom training over a twenty-year period. The CD resource kit has been designed according to performance-based behavioral learning principles and the course and module objectives support the skills required to manage projects successfully. A subsidiary goal of the project has been to develop a model for future distribution of learning resources in various media, both in print and electronically, on CD and over the Internet. The model attempts to address the training needs and the technological constraints that exist in the developing world. The complete resource kit has 12 modules: 1. Understanding the Project and Project Management; 2. Structuring the Project Organization; 3. Building the Team; 4. Analyzing the Project Context; 5. Refining Objectives, Scope, and other Project Parameters; 6. Preparing Work Breakdown Structure; 7. Planning and Scheduling with the Critical Path Method; 8. Obtaining Management Approval and Support; 9. Designing Control and Reporting Systems (Scope, Time, and Cost); 10. Organizing Procurement; 11. Executing and Controlling the Work; 12. Terminating the Project.

Content and Process

Developed to help instructors design and deliver course in the classroom, each topical module includes performance-based objectives, module and session outlines, scripted "sample" lectures and visuals, case exercises, teaching notes, solutions sets to exercises and case studies, optional readings, and a glossary of terms. Capturing these materials electronically and "repurposing" them has provided the opportunity to improve their instructional effectiveness, the coherence of the course package, the coverage of the learning activities, and the design of the printed page. This CD project has yielded an improved print-based product, a new electronic product, and a model architecture for distributing learning materials electronically on CD-ROM.

Functionality

The project aims at providing maximum functionality to the classroom trainer as well as to the self-directed learner by drawing on the recent presentation and electronic publishing technologies while at the same time staying within the technological constraints of the developing world. It is possible to search and sort the materials by topic and by type of learning resource (i.e., case study/exercise, lectures, readings, and combinations of these categories). Any material or combination of materials may be printed out on a laser printer while retaining a consistent format. Overhead transparencies may be printed out or projected in class directly from the CD. The electronic files of the lectures and cases can also be downloaded into standard word processors for modification. Alternatively the materials may be previewed and browsed on the computer for purposes of self-directed learning, although this is not the primary intent.

Architecture

All materials are housed in an object-oriented database that provides a system for managing, searching, and browsing media elements including text, audio, 3-D and video. It has a built-in navigation system that is separate from both the interface and the content, which allows interface and content to be changed easily without complicated programming. It can also be used to run Web services. Visuals created in Powerpoint may be projected by launching the Powerpoint viewer. Visuals and all other text materials are captured as PDF files and may be viewed, searched, and printed using Acrobat. Printed "lectures" may be browsed by scrolling the text in one window with visuals in an adjacent window.

Learning by Doing - Teaching Hypermedia Hyperactively

Wren M. Bump, Ph.D.

Adult novices are very interesting and challenging to teach. In the area of computers and computer concepts, novices can be surprisingly low on prior knowledge, or else they are so filled with anxiety that any relevant prior knowledge is blocked. In either case, the teacher needs to use a variety of teaching strategies that have been proven to be effective in helping the learner construct and apply new knowledge. Three strategies were applied to the specific concept of "hypermedia": accessing and building upon prior knowledge; using metaphors in teaching new concepts; and collaborative grouping.

Strategies for Teaching Hypermedia

Accessing and building on prior knowledge is fundamental to any lesson or any activity that involves learning something new. In order to allow learners the opportunity to feel comfortable in learning about hypermedia, the first step was to examine the word "hypermedia". The learners have heard and used the word media in their everyday lives in reference to television, newspapers, and videos. They have also used the term "hyper" when referring to an unruly child or someone who cannot stay on any one task for any length of time. So a short review of these terms, combined with a class discussion of "hyper" people that the learners knew, provided a foundation of prior knowledge on which to build.

The next strategy used was a metaphor for the hypermedia program to be introduced. The software program used in this activity was HyperStudio. This program has an index card structure, so the metaphor of a stack of cards enabled the learners to understand the nature of HyperStudio.

The last strategy used in this lesson was collaborative groups. The students were grouped and given various tasks so that they could problem-solve, experiment, and construct their own meanings of the term "hypermedia". They were able to feel comfortable with the task since they were not working individually.

Activities for Teaching Hypermedia Hyperactively

All of these activities were done in a large open area. Step One: The students were divided into three groups. One group was the "New" group; one group was the "Linking" group; and one group was the "Input Data" group. The "New" group was in charge of creating any new object such as New Card, Add a Button, Add a Graphic Object, or Add a Text Object. The "Linking" group was in charge of connecting the linked objects with tape and yarn. The "Input Data" group was in charge of entering text.

Step Two: The groups were each given task cards which described what they were going to be creating. The "New" group had a stack of posterboards from which they cut buttons, text fields, or graphics. A whole piece of posterbaord was used for each card. Their first task was to create a stack with five cards, so they lined up five pieces of posterboard on the floor. Their next task was to create two text fields on the first card - one for the title of the stack and one for the creators of the stack. One group member of the "Input Data" wrote "The Three Branches of Government" in large letters in the text field at the top of card one and then wrote "Created by the Instructional Technology Class" in the other text field. Another member of the group placed these fields on card one. They could be either taped or glued. (Taping would be a more appropriate representation of a text object.)

The next task required all three groups to work together to create a button that would be linked to the next card. The "New" group created the button. The "Input Data" group labeled the button. Then the "Linking" group taped one end of the yarn to card one and then taped the other end of the yarn to the second card.

BEST COPY AVAILABLE

On the second card, three buttons were created and labeled "Executive", "Legislative", and "Judicial". The groups worked together to link these to cards three, four, and five. Then a button was created and placed on each of those three cards that would link them back to card two. The "Linking" group made sure that the other groups knew that the one link from the menu card to the individual card could not be used to go back to the menu.

Other text fields and graphics were created and placed on the cards. Then each group had to summarize and report their group's major responsibilities and any problems that they encountered. This part of the process helped prepare the learners for creating a stack of their own on the computer.

Conclusion

By making a game out of the creation of hypermedia, I was able to prevent my older students from being confused, frustrated and defeated. By using this activity, I had something concrete to refer them to, if necessary, as they completed the computer task. The whole activity took less than 45 minutes and was well worth the time. One added benefit of this activity was that it developed student leaders who were confident and comfortable helping their fellow classmates. I noticed that many of those students quickly accomplished the computer task of creating a four card stack with many links, transitions, and actions. They were then able to help the slower students construct their stacks in the HyperStudio program.

Crumbling Walls: Hypermedia Sketchbooks in Art Education

Christopher Burnett
Kansas City Art Institute, USA
Photography-Video Department
cburnett@gvi.net

Abstract: "Crumbling Walls" uses an experimental hypermedia program, MediaScraps, to speculate on alternative methods of sketching for media artists. It proposes that similar processes of projection and working over visual ideas, that began with Leonardo da Vinci's sketchbooks, can occur using hypermedia scrapbooks and collaborative computer archives. Features of the software, designed for an intranet, are descibed as well as the educational context of using it. The program's purpose is to help foster ideas --- not in producing finished work. However, this "secondary" medium raises primary questions on the nature of personal and public expression.

An important task for art education is to encourage methods, means and spaces where developing artists can work out their ideas. Sketchbooks, scrapbooks and diaries are perhaps the most ubiquitous and wonderful portable accoutrements of the visual artist. They constitute the ready-at-hand sidearm drawn not at precise, preexisting targets but rather at the fuzzy aims and purposes which are always in a state of becoming.

The practises of sketching that transcend planning purposes and go further into the primary creative process were invented by Renaissance artists. E. H. Gombrich points out that Leonardo Da Vinci's notebooks suggest how artists might adapt drawing to new purposes: away from the exactitude and specifying of medieval form and towards more open processes of perceptual and conceptual discovery.[Gombrich 1966] Leonardo recommended looking at crumbling walls because one could find within them stange inventions. Consequentially, he extended the experiments with walls and perceptual projection to the sketches of his notebooks. According to Gombrich, not only did Leonardo's process of discovery lead to a dreamlike loosening of controls but also to the persistence to keep on creating, never accepting any form as final. I am proposing that a similar process of projection, working over and assimilation of ideas can occur using digital sketches, hypermedia scrapbooks, and collaborative computer archives.

At the Kansas City Art Institute, my colleagues and I have long sought alternatives to traditional drawing and sketching for the students entering school and our department. We recognize that drawing is a crucial experience for visual artists, and most students gravitating toward the media arts (film, video, photography and computer art) do have extensive drawing experience from high school or within the foundation curriculum of the college. But in a media society, drawing no longer provides an absolute, universal benchmark for conceptual skills or their awareness of visual culture. We need to look at other methodologies, especially for developing students of media, to reveal the level of their visual thinking.

I am not only suggesting that the methodologies be broader, but that they be more germaine to the specific interests of the student and to the nature of the society in which we live. If, as artists, we understand that culture moves according to a logic of optical representation, mechanical reproduction and cybernetic dissemination, then the way we develop our ideas should work according to this logic as well. Without throwing away our sketchbooks, we need to find technological tools to supplement them and extend them by analogy. Looking at the personal sketchbook/notebook of art school students is a good starting point.

The prototypical art school student notebook is a medium-sized hard bound folio of white, unlined sheets. The students fills one page after another with accumulations of personal notes, lists, drafts of writing, classroom notes, diagrams, doodles, visual-amusements, pasted scraps, photographs, project scenarios, storyboards, sketches and elaborate renderings. When the pages are filled, the notebook is shelved next to prior volumes, and a new one begun.

These are trustworthy, useful and revered volumes. They a inexpensive, durable, portable, easy-to-use, and both standarized and uniquely personal. A students entire educational career and personality is encapsulated by them.

But there are shortcomings to the venerable notebook, and the aspiring media artist might wish to augment them with the power of computers and imaging technology. They would then be reconfigurable, editable, infinitely expandable, searchable, and, importantly, in a mirror-like form to media culture. Already, media artists are adapting their Foundation sketchbooks to function as repositories for their image fragments, photographs, clippings, classroom notes, and dramatic scenarios.

In the Sophomore Introduction of the KCAI Photo-Video Department, we are experimenting with a hypermedia program to erect this kind of digital scrapbook where media artists can sketch out their ideas in their own terms. Before I describe the software we have developed, a description of our Sophomore program and the events leading up to the project would be useful background.

The Sophomore program is designed to give the student all the basic skills necessary for advanced work in the Photography-Video Department. These skills include a black and white photography, color, alternative processes, lighting, large-format photography, video editing, audio, digital image editing, layout, and multimedia authoring. Besides Photography and Video, there is a third section, Media Art (which I teach) that covers computer practices as well exploring the relationship between fine-art culture and the culture of mass-communications. All sections encourage the thinking skills and independence necessary for students to perform mature, self-directed work in the junior and senior workshops.

Toward these goals (of working independently), I saw a need for ways that students could loosely organize and display their work-in-progress. In to my section of the course, observing and documenting media culture are important, and many assignments ask students to clip and digitally scan images that illustrate weekly themes, such as print-reproduction syntax, pseudo-events, changing persona in mass-celebrity, and so on. We needed a means of organizing these digital clips as well as a forum for their display. In addition, the class works in a variety of media types -- still picture, quicktime movie, QTVR, audio, and text -- so that a digital scrapbook must be as flexible in file type as in subject matter.

In the Fall 1995, I initiated the "MediaScraps" program in Apple Hypercard and Heizer Windowscript. It was designed simply as a front end and viewer for the all the above-mentioned types of digital files. A palette presenting lists of folders and files was at the center of control: simply click a folder to display its contents; double-click a file to display it center-screen. The heart of its utility was in the flexible manner that this brower works with the Macintosh Finder (through AppleScript): remove, add or rename files and the contents of the control palette instantly update to the new state of affairs. After an initial prototype, I ported the program to Allegiant Supercard, because of its integrated windows environment, menu creation tools, color support, and external software for working with directory files.

From this simple beginning, the program has evolved into a full-blooded program with a prodigious feature-set, which I will itemize: As many as four-windows can be open at open time; the pictures are scaled accordingly. The control palette can take a number of configurations: It can display the file type and file size. Icons can be displayed on the fly. The user can select a filter to list a particular file type. Importantly, user-information can be added to the files. Keywords can be added through a special window with an authority list based on categories of the course material. Students can add loose comments, too, in a couple of ways: by keying in a comment or by digital voice recording. Either form of comment is displayed or played back, respectively, by a special window along the bottom, by synthesized speech, or by regular audio playback. Comments accumulate for each file and an arrow-button permits one to browse through them. The standard suite of four windows will display any document type, but there are other windows for special circumstances. There is a "QTVR special" window that supports the full range of QTVR capabilities such as auto-panning and zooming. There is a icon window, where icons are drawn together from any folder and arranged into layouts. The icons retain links to the original files (as long as the file name and file location are not changed); slideshows can be played back, and file sets can be copied out to separate folders. Lastly, the environment is customizable with the ability to change and edit the backdrop pattern and to set preferences for the feature sets in operation.

This latter ability to inactivate certain features was called for by the need to keep the simplicity of the program's core vision: an easy-to-use digital scrapbook. In keeping with the need for simplicity, I have retained the way in which the program works with the Finder and its one-folder-deep limitation. To set up MediaScraps, you drag the program file to a folder containing the file folders you wish to access; these folders cannot contain other sub-folders. Since no file-specific data in carried by the program, if anyone desires to access another set of file folders, he or she simply copies the program to the new context.

This balance of simplicity and complexity also becomes an issue for me working as programmer at the level of code, too. The scripting of authoring tools like SuperCard offers non-professional programmers the ability to try out code and make modifications immediately. Their object-oriented structure encourages a modular approach to design and an incremental path of development toward complexity. Students continually give me feedback on bugs, features, and interface design and a number of change have been made in response to their ideas. Indeed, even at the level of code, MediaScraps retains the spirit of drafting and exploration carried on by the entire class.

In summary, in its design, MediaScraps involves sketching metaphorically by conceiving form through a process of trial-and-error, evolution of details and the counter-movement of discovering and retaining core structure. In the usage of MediaScraps, sketching is primarily a matter of montage, arranging and comparing. In the future, drawing tools can be implemented to transform graphics as well. But, there are still basic levels of "sketching" (as a metaphor) remaining in which I can draw concluding speculatons.

As a class project, MediaScraps comprises a collection of personal scrapbooks, and in its aggregation, may be thought of as an archive of diverse material.

Media artist must learn from archives (photographic, film or otherwise). Loose collections of images in archives are, in a sense, their crumbling walls. In the darkness of archives, associations may be found between items that they never had (or will ever have) in the public light of galleries or in publications. This place of faint links and sparking associations will later illuminate the screens, video rasters, or frames of regular display spaces.

Recently, I have been gratified to see specifically how MediaScraps has provided in action an archival space for issuing images into the light of day. Our Department is currently producing a multimedia work about ourselves and our work. MediaScraps is in action collecting and organizing the diverse material and content of the production. (We are using mTropolis for the final program because of its object orientation and its ease of cross-platform development.) I have adapted the program to the functions of archival management with custom database tools. In keeping with the document orientation of MediaScraps, the data is written to the resource fork of each file (as well as to an external text file for backup) rather than to the cards. There is a capable search engine that retrieves both data from the resource fork and references to the original files.

Though these database capabilities are still being developed, the archival possibilities and powers of MediaScraps are being felt. At this stage, we are considering ideas of classification, cross-referencing, and image description that are leading to the discovery of the nature of visual information and knowledge. Like an archive, MediaScraps is a practical means-to-an-end (the end being the CD-ROM) but may also be viewed, like a library, as a rich cultural artifact.

Libraries, even if private, always point to public knowledge, and this awareness leads me to speculate about the value of MediaScraps as a rewiring of the personal scapbook to become a medium of collaboration and communication among artists. The basis of the shift is powerfully embedded in the archetypal student sketchbook: a record of personal diaristic thoughts, yet also, through decorated covers, an outward expression of identity and status. Leonardos sketchbooks were emphatically personal. They were even encoded by reverse writing in order that others could not easily read them. Yet they stand as monuments to the collective spirit of innovation of the Italian Renaissance. Libraries are similary ambiguous in being places of personal and private retreat, yet they embody the most public of impulses toward social understanding of the world.

MediaScraps, similarly organizes ideas for the self but also manifests them to others. The scrapbook-archive is located on the schools central server where students can access it anywhere on the local area network (intranet). Central, yet dispersed, students have a private window on their own scrapbooks in view of those of their colleagues. They may add comments and keywords to others scraps as well as their own. In view of the changing nature of social communication through digital technology, it is important that artists develop their work at the edge of the increasingly blurred boundary between public and private life.

In conclusion, MediaScraps has shown many exiting of possibilities, but as an evolving sketchbook, there are still new ideas to explore; new lines to draw. So far, we have realised the intention of finding tools that encourage development of artwork through projection, association, collection and collaboration. But, hypermedia tools may be useful in retrospection as well. Artists statement may be used not only for self-promotion, but also for self-understanding. Already designers use portfolios on CD-ROM or Web pages to sell their wares, but educational possiblities for artists exist here, too. The future step for MediaScraps is to produce an enlightening hypermedia-form of artists statement.

A Study into the Future use of Synchronous and Asynchronous Technologies in the Distance ESL Education Area with an Emphasis on Collaborative Learning

Andrew Burrell, The Australian Centre for Languages, Australia, Educational Coordinator, bandrew@dot.net.au

Abstract: Synchronous and asynchronous technologies can be applied to the *Teaching-Learning Cycle (TLC)* pedagogy to provide an effective collaborative distance ESL model where the focus is on learning with the assistance of technology. This pedagogy is learner centred and moves from known contexts (vocabulary, functions and grammar) to the unknown with scaffolding provided to the learner as needed throughout the course of learning. Collaboration ensures that the learner has ownership and is responsible for their learning. The translation from a one site to a multi site classroom affects the types of distance education technologies used. Research demonstrates that many technologies must be employed to effectively implement the TLC.

Using Synchronous and Asynchronous Technologies in Distance Adult ESL

The Teaching-Learning Cycle (TLC) [Hammond, Burns, Joyce, Brosnan and Gerot 1991] provides a basis and framework for planning an effective series of lessons in the language and literacy classroom. It incorporates tasks that concentrate on the social language functions of text types whether they be spoken or written. Learners learn about the language through the modelling and deconstruction of texts and by drawing on the shared understanding of the schematic structure and grammatical patterns of the text-type being taught. After much text analysis, learners jointly construct the target text moving onto independent construction when they understand the necessary text-type features. Throughout each stage of the TLC, collaboration is an essential feature. The four macro skills reading, writing, speaking and listening encompass a 'whole language' approach to ESL teaching in an integrated fashion and not in isolation.

The TLC consists of four stages with the first stage being *Building the Knowledge of the Field*. This stage provides the cultural context, shared experience, control of relevant vocabulary and grammatical patterns for the target text-type. The next stage *Modelling of Text*, provides the cultural and social function of the text. Schematic structure and linguistic features are highlighted in the target text. The next stage *Joint Construction of Text*, provides learners with a chance to use the schematic structure and linguistic features of the text collaboratively together with their combined knowledge of the field or context to practise re-creating the text-type. The final stage *Independent Construction of Text*, allows the learner more autonomy to construct their own texts using the context and structures provided throughout the TLC. In translating the teaching environment to a telelearning environment, the macro skills are incorporated into representational forms, that is, *visual, graphical, textual, aural and data representational forms*. Some of the forms are best suited to synchronous technologies while other forms function best with asynchronous technologies. To utilise the TLC in a collaborative learning environment, careful use of both synchronous and asynchronous technologies are necessary to foster effective distance learning.

The table below demonstrates how synchronous and asynchronous technologies were applied to the TLC.

Stage 1 Building the knowledge of the Field			
Reading	**Writing**	**Speaking**	**Listening**
Visual/Graphical: View video/pictures/diagrams to set	*Textual:* Brainstorm ideas as a group onto	*Aural:* Talk and share experiences with other	*Aural:* Listen to each other's experiences from

the context. *Textual:* Read a variety of authentic texts. • *Asynchronous*	a common 'white board' • *Synchronous*	members of class • *Preferably Synch.*	the class and the teacher. Listen to the text in use. • *Preferably Synch.*
Stage 2 *Modelling of the Text*			
Visual/Graphical: Review videos/pictures to identify examples of the text-type so context is reinforced. *Textual:* Read model of the text, help given to identify key features • *Synchronous*	*Textual:* Collaborate and brainstorm ideas as a group onto a common 'white board' • *Synchronous*	*Aural:* Talk and share ideas, collaborating with other members of class. In small groups and pairs discuss features of text. • *Preferably Synch.*	*Aural:* Listen to each other's ideas from the class and teacher. Collaborate by listening, sharing & identifying features of the text-type. • *Preferably Synch.*
Stage 3 *Joint Construction of the Text*			
Graphical: Small group/pair work using collaborative activities to reinforce staging of similar texts. *Textual:* Small group/pair work constructing grammatical examples within context. • *Synchronous*	*Textual:* Small group & pair work using collaborative activities to reinforce staging and grammatical features of similar text-types. • *Synchronous*	*Aural:* Small group/pair work in collaborative activities to reinforce the features of similar texts. Practise the text-type & similar text-types orally if spoken. • *Preferably Synch.*	*Aural:* Listen to each other's ideas in small groups & in pairs. *Aural:* Collaborate by listening, sharing & constructing the text-type. • *Synchronous*
Stage 4 *Independent Construction of the Text*			
Graphical: Individual activities to reinforce staging of similar text-types. *Textual:* Individual work constructing grammatical examples within context. • *Asynchronous*	*Textual:* Individual activities to reinforce staging and grammatical features of similar text-types. • *Asynchronous*	*Aural:* Individual activities to reinforce the features of similar texts. Practise the text features. • *Asynch. or Synch*	*Aural:* Listen to teacher and other's ideas. *Aural:* Individual listening & construction of the text-type. • *Asynch. or Synch*

Synchronous technologies trialed incorporating *textual and/or graphical representational forms* included shared electronic whiteboards, IRC, Livechat and MOOs. *Visual and aural representational forms* included ISDN audio conferencing and video-conferencing which allow effective but sometimes costly synchronous collaborative work. Internet based video-conferencing provided a 'form' of synchronous collaboration. Remote control programs such as Timbukto allowed further demonstration and collaboration as learners and teacher controlled each other's machines. Asynchronous technologies trialed included e-mail, newsgroups and threaded discussion forums.

It is common practice to establish protocols for any type of telelearning, it is essential to have the protocols clearly defined and understood beforehand when setting up sessions. Unfamiliarity with basic computer literacy skills such as typing need to be taken into account. Discourse problems can occur in the use of text based programs, with learners often have trouble discussing in written form The problem involves the sequencing of replies to the chat space. This is directly affected by the number of participants involved in the group. Replies arrive at the chat space out of sequence as the time lag between nodes affected transmission rates. The use of a moderator helps to address this problem. If available, one nominated person could enter the group's textual comments rather than on an individual basis. Video-conferencing can be effective but needs to be highly structured at first to allow user familiarity to overcome the discourse problems experienced with turn taking. A structure needs to be set in place so that everyone does not speak at once. The nature of the session needs to be decided well in advance so that the intended outcomes are realised.

The TLC requires collaboration at nearly all levels which in turn requires mainly synchronous technologies. Internet bandwidth is still the major stumbling block for less costly, effective oral/visual/graphical collaboration in real time. Textual collaboration is useable but has many discourse problems that need to be addressed. With an ever expanding range of technologies, cost effective real time collaboration will be within reach.

Abstract: The "Integrator" is a part of BioBLAST, a CD-ROM course supplement package integrating concepts of biology and systems design as applied to a high school biology class. Students are presented with an authentic task: to design and manage a controlled ecological system that will sustain life for six astronauts on the lunar surface for a period of three years. Students participate in (1) basic laboratory experimentation, (2) using advanced media for researching background, and (3) formulating questions and carrying out investigations to reach answer(s). The very richness of the activities requires that students carry out – at critical points in the learning cycle – exercises that both consolidate gains from the hands-on activities and mediate the transition of data analysis to concept formulation in the learner. The "Integrator" is a simulation-driven "cognition enhancer" that mediates this all-important step in sound scientific reasoning.

1 Background

The BioBLAST Project (sponsored by NASA and developed at the *Classroom of the Future*, Wheeling Jesuit University) consists of educational software (simulations, microworlds, and interactive multimedia) based on NASA's Advanced Life Support (ALS) research being carried out at several NASA Centers. Sustaining humans in colonies beyond earth's environment requires a balance among components and systems. Focal points of research include: (1) plant production, (2) human requirements, and (3) resource recovery. BioBLAST consists of a six-week curriculum supplement -- featuring scientific investigation, laboratory data collection, and creative problem solving -- built on the scenario of designing a balanced, closed biosphere to support a crew of six living on the lunar surface. Virtual Reality (VR) multimedia increases motivation by presenting a high-fidelity walk-through of the lunar environment. Additionally, a variety of simulation-driven enrichment environments provide opportunities for students to extend the empirical activities of the lab and background knowledge gained in the classroom to the challenging final exercise of creating and managing a biosphere.

2 The Integrator: Teaching Strategy Acquisition through Guided Simulations

The "Integrator" is a cognitive tool that helps students make the important transitions between collecting data, drawing conclusions, and recognizing and applying concepts. This "cognitive tool" puts the student-team in the role of a systems specialist/control engineer who monitors a functioning ALS environment. As an inquiry tool, its "metaphor" is one of systems operations and trouble-shooting. The student team monitors a control panel showing the major "living" elements in the habitat and current status (or balance) of common resources (water, carbon dioxide, biomass, grain, oxygen, and liquid nutrients). A "library" of authentic problems/scenarios present alerts and alarms (system imbalances and prognoses) for the students to work with, appropriately selected to match the activity strand leading up to the session with the "Integrator." From the initial fault report, the students move through structured workspaces that mediate expert behavior patterns for troubleshooting and for evaluating, applying, and adapting a repair that brings the system back in balance.

The "Integrator" uses a hybrid approach for interactive instruction. Part of the guidance comes from that adaptive tutoring that works with the underlying simulation engine and part comes from the powers of reification (or representing complex mental processes as manipulable objects on the computer screen). Four structured workspaces in this tool (1) accommodate deficiencies and thereby reduce frustration for the students, (2) enrich the environment and thereby sustain motivation, and (3) explicitly model strategic intellectual processes and thereby provide the scaffolding that allows the fledgling student to attempt increasingly more challenging levels of participation.

- *Workspace One: List Probable Causes* -- Students complete a statement of cause and effect: "The <specific condition in the alert> exists when . . ." . In order to list all possible causes, the students select from pull-down menus an agent (crew, plant, microbes, etc.), a resource (H_2O, CO_2, etc), a role (consumption or production), and a direction (increases or decreases). This manipulation results in a research agenda – a set of possible causes for the reported condition. The workspace encourages systemic thinking and reinforces the ideas of "dependent" and "independent" variables in a cause/effect statement.

- *Workspace Two: Investigate and Examine Evidence* -- This second workspace helps the students to examine sequentially the potential causes by analyzing evidence from selected attributes for the crew, plants, and microbial elements of the system. In essence, the students perform observations and collect data from which they infer errors. Elements operating out of a defined max/min range can then be flagged. Visualization (thinking frames) and inquiry tools in the workspace help students to see relationships while analyzing data and to draw inferences about the source(s) of the imbalance.

- *Workspace Three: Select "Best" Solutions* – Having empirically proven the cause(s) for the imbalance, the students now construct a repair plan. Once again, pull down menus offer a constrained set of options, allowing students to construct a sentence that indicates a change in the system (e.g., "Decrease grain intake."). Since this is a dynamic, multi-dimensional system, several repairs are possible. Thus, students evaluate each possible course of action in terms of a two-dimensional matrix: high cost/low cost and high gain/low gain. Placing each course of action within one of the four cells helps students to judge actions within a larger frame of reference.

- *Workspace Four: Apply Solution and Adapt* -- In this workspace, the students apply their repairs in the sense that they set conditions, run the simulation, and observe the changes over a selected period of time. Visualization and inquiry tools demonstrate effects in numeric, verbal, and graphic formats. This workspace introduces the concept of "duration" to the problem. Because of the complexity of the ecosystem, some changes will take effect too late to save the elements at-risk in the environment; others will work initially, but over time create side-effects that precipitate yet another (perhaps more dangerous) imbalance. This workspace encourages very sophisticated thinking in that it fosters an awareness of multivariate processes occurring (and perhaps reversing) over an expanse of time.

The Virtual Learning Center: Distance Education on the Web

Terrell N. Chandler Ph.D.
Galaxy Scientific Corporation
Atlanta, GA USA
tchandler@galaxyatl.com

Abstract: This paper describes a demonstration version of a Virtual Learning Center developed at Galaxy Scientific. The intent of this paper is to illustrate possibilities of training over the World Wide Web through a virtual campus. Advantages to taking such an approach will be highlighted, as well as, issues that one must consider when implementing such a facility (See CD-ROM version of paper for discussion of advantages and issues). During the conference presentation the Virtual Learning Center will be demonstrated.

Introduction

With the constant pressure of down-sizing, corporations and the military find themselves in positions of having to train their personnel to perform broader ranges of tasks. Personnel are expected to be more skilled in more areas while fewer dollars are available to meet these training needs. Distance Education is enjoying a revitalization of interest among corporate and military leaders, because they recognize the potential benefits as a low cost solution to their training needs. Distance education is a pedagogical approach where people engage in educational activities without having to be at the site where the instruction is occurring. Instruction, resources and students can be distributed across many different locations, and are usually connected together by technologies, such as computer networks, satellite dishes and telephone lines. The vision for the distance education development group at Galaxy Scientific (Galaxy), is to capitalize on the technical capabilities of the World Wide Web (WWW) to create a Virtual Learning Center (VLC) for continuing education of professionals.

The Virtual Learning Center Concept

Upon entry to the Virtual Learning Center, students find themselves viewing a school campus (Figure 1). The campus is divided into four conceptual categories of activities: administration, classes, resources and recreation.

If individuals want to participate in a class they first go to the registration area to sign up for the class or see what classes are being offered. When they register for a class they are placed on a class mailing list where they can send and receive mail to and from their instructor or other class participants. If the class uses video or audio, the student is instructed to go to the audio/visual room in the resources area. This is where students can check out the software and download a list of the hardware they will need to participate in the class. Instructions for implementing these programs are provided in this room, as well as a hot-line to address implementation difficulties or general technical questions. The type and sophistication of the equipment will change with the type of activity that is planned for the class. For instance, a lecture may require real time audio and a presentation "white board" that supports writing annotations on photographs or graphics. A lab may require two-way video between students and instructors.

Scheduled classes occur in the classroom area. In the event a student misses a class, the student can make up the class by visiting the class archives where he or she may check out the appropriate session. To download curricular materials or journal articles or jump to other reference sites, students visit the class materials checkout or references in the resource area. To study and take tests, students visit the testing area.

Recreation is where more informal interactions may be found. The cafe is a meeting place for interest groups to gather and chat about various issues. Announcements for new classes and other community activities are posted on bulletin boards in the announcement room. The game room is a place where people can experiment with role playing through MOOs and MUDs or other simulated environments related to their area of study. Finally the atrium is a place where students can deposit their finished products for others to appreciate. These products could be generated either through a formal class or spawned informally at lunch or in the game room.

In the above scenario, static and dynamic information are seemlessly integrated. At the library, for instance, students read and download articles. At a lecture or conference, where dynamic interaction is desired, two-way audio and video technologies may become the norm. The more general term for this type of facility is computer-mediated communication. Computer-mediated communication is generally divided into three areas: conferencing, informatics, and computer assisted instruction [Collins, Berge; 1995]. The VLC demo developed at Galaxy supports facilities in each of these areas. In the realm of conferencing, such facilities as real-time lectures using a radio talk show style of delivery, bulletin boards for announcements, and interactive chat rooms for class discussions and student-to-student collaboration is available. In the area of informatics, the VLC provides direct mailing of class materials to students through a MailDoc facility. Links to information sites, archiving of class lectures and discussion sessions, and posting of finished projects can be read, played or downloaded through reference and audio/visual pages. These facilities will contribute not only to instruction, but also to the analysis of that instruction for research and evaluation purposes. Computer assisted instruction currently includes on-line testing. In a more experimental realm, the introduction of role-playing and problem-solving activities through on-line ITS, simulation labs or gaming facilities is possible. A Virtual Learning Center approach to Distance Education has huge potential for training. There are many design and implementation issues that need to be address to insure success; however, given the natural modular structure of the VLC, many interesting solutions to distance education across the internet can be accomplished today.

Recent advances in communications, networking, and computer technology have delivered capabilities to today's classroom computers that overwhelm what was considered possible only a few years ago. Advances in desktop virtual reality, real time rendering, and worldwide Internet linked computers have created an explosion of new market opportunities. It is no wonder that today's students spend so much time on the computer. Multi-player network games, which execute in real-time and contain virtual worlds, offer tremendous stimulation and entertainment for the student. These games create environments where students can challenge the computer as well as other students in increasingly realistic scenarios.

With the advent of the Internet coupled with the recent explosion in desktop interactive visualization capabilities, the ways in which information is transmitted, and the ways in which people interact, and receive information, are also changing. These new modes of processing information need to be accounted for in the educational process to better prepare students for the technological challenges outside the classroom, and to more effectively educate students inside the classroom.

To this end, Mission Research Corporation's DzignLight Studios (MRC), in conjunction with the Space Training And Research Center (STAR) of the California Spaceport Authority at Vandenberg Air Force Base, is developing a Multimedia Interactive Animated Computer Training (MIACT) program under the project name "Apollo 2000".

MIACT is a learning device for students that consists of stand-alone educational modules that combine mathematics and science education with an interactive multimedia environment. The platform of MIACT is a space mission. The primary components are spacecrafts and mission control centers on earth. A conceptual diagram of MIACT is shown in Figure 1.

. . .

Figure 2 MIACT Interconnect Block Diagram

MIACT incorporates today's technology (including the Internet, 3-D animation, virtual reality, and interactive multimedia) within a real-world mathematics and science learning environment. The modules will teach varying disciplines, including mathematics, physics, chemistry, etc. A particular module can emphasize one discipline, or it can be multi-disciplinary. The modules can be used as a supplement to course lectures, as an assignment, or to teach a laboratory sequence.

The primary components in MIACT are space-crafts and mission control centers on earth. Students in different classes, or at different schools, run a spacecraft component or a mission control center component. Students working on a particular component interact to establish priorities and appropriate courses of action. This requires individual and joint research and problem solving of scientific and mathematical tasks. Students decide who will perform designated tasks (e.g., command, guidance, propulsion, defense, personnel, etc.). During the course of a mission, the students in a component must work together, and interact with the other components run by different groups of students.

To successfully complete a mission, the students must carefully plan the stages of the mission, conduct necessary research, and perform calculations before the mission begins. The students are shown aspects of previous successful and unsuccessful missions. This serves to introduce students to the multimedia format of the educational modules and stimulate interest, and motivate them to do the necessary preparations for their mission. The students are then shown a rudimentary simulation of their mission. The students research will involve mathematics, physics, chemistry, biology, astronomy, etc. Students must perform the necessary calculations and preparations for the mission. They must work as a team to develop and understand the different aspects of the mission design phase. They will therefore be performing analyses and tradeoffs.

If their pre-mission plan is in error, problems due to these errors will be experienced during the mission. The students will have the opportunity to learn from these errors and make corrections during the mission. If the pre-mission plan is sound, the plan must be successfully implemented during the course of the mission. This will require timing and coordination between the members of the spacecraft and the mission control center. If the operations (e.g., using a gravitational field to control flight path) are not implemented successfully, then errors will be experienced.

In addition to these deterministic errors, there will be random errors generated by the module. These errors will include failure of spacecraft components, communication interference, meteors, etc. The students will also have the opportunity to learn from these errors and make corrections during the mission.

MIACT will be used for teaching mathematics and science to pre-college students in an environment that stimulates learning based on situational contexts, involving students working individually and collaboratively, in small and large groups, using concrete materials. MIACT will help students to think and reason through the implementation of mathematical and scientific ideas and tools, communicating ideas, and gaining confidence in their abilities. This will help the performance of students in mathematics, science and engineering courses.

Current Prototype Development Effort

A prototype module is under construction, sponsored by the Department of Energy. The primary educational emphasis will be in the area of mathematics and science. The platform will be designed to run from a single computer, and from two computers. The Phase I effort will demonstrate the state-of-the-art in multimedia and PC-based virtual reality technology.

Intranet Learning Environment for Junior High School's Computer Course

Guey-Fa Chiou
Department of Information and Computer Education
National Taiwan Normal University
Taipei, Taiwan
E-mail: gueyfa@ice.ntnu.edu.tw

Abstract: We are developing a school-based intranet learning environment for supporting junior high student's learning of computer concepts. We believe that our evolving intranet environment will demonstrate the usability of integrating intranet technology into junior high school campus and will provide a rich environment for studying the rationales, models, and strategies of network-based on-line learning.

Introduction

We believe that Intranet technology is mature enough to let an organization (such as school) build an internal network environment. And we also believe that the independent Computer course for junior high students should have new learning rationales and models. Based upon the opportunities provided by the new Computer course and by the maturing intranet technology, we plan to integrate the intranet technology into the new course to construct an network-based learning environment, an environment students can have different learning experience.

Design and Development

Technology: We use Web server, Mail server, Workgroup server to set up a server cluster. Video server will be added later.
Learning Materials: There is an official computer curriculum guideline for junior high schools. It has twelve chapters with the emphasis on the basic computer concepts, basic computer operations and computer applications [Chiou & Wu 1996]. It is a computer literacy curriculum. We use prototyping approach to develop the material. Based on our experience, we believe that several required principles have to be followed: (1) avoid the unnecessary classification, (2) avoid unnecessary jargons, (3) example first, abstract explanation second, (4) use analogy carefully, (5) always consider average junior high student's reading comprehension ability, (6) provide deep knowledge for some students (layering the computer knowledge and skills), (7) use new and correct information, (8) do not overemphasize the underlying computer theory (phenomenon first, theory second).
Learning Activities: Currently our intranet environment support browsing, emailing, and asynchronous discussion. Synchronous meeting (such as text conference, audio conference, whiteboard) will be added later.
Learning Aids: We plan to develop on-line computer dictionary, on-line private notebook, and on-line public notebook.

Learning Information Management Utilities: Our intranet learning environment will embed login, tracking, teacher, on-line testing, and portfolio utilities.

Human resources: A successful school-based intranet learning environment will be labor-intensive and mind-intensive. During the process of design and development, it is necessary to consider human resource issue deeply and clearly. Technology is only and always a tool for people, it is us the people who makes the intranet work.

Research Issues

Rationale issue: What learning rationales can be used to guide the development of school-based intranet learning environments? Is it possible to have some new learning rationales? For example, we might try to integrate the existing learning rationales, such as constructivism and community of learners, to form an optimal rationale for network-based learning environment [Chiou 1996].

Strategy issue: What learning strategies are appropriate for the on-line intranet learning?

Moderation issue: What is the optimal model for moderating a domain specific intranet learning environment?

Tool issue: What learning tools or aids should be developed to help student's learning?

Further Considerations

School-based intranet learning environments are the foundations for constructing the Internet learning environment (a form of distance learning). And subject-specific intranet learning environments are the foundations for building school-based intranet learning environment. Constructing a high-quality subject-specific intranet learning environment is the first step toward high-quality on-line virtual learning, even an international on-line learning. And opening the school intranet and connecting it to the community network will be a great opportunities for students, parents, family members, schools and communities. Looking through the intranet window, we could see the opportunities for educational services and educational researches.

ABSTRACT: A group of cognitive psychologists identifies effective learners as self-regulated learners who are metacognitively, motivationally, and behaviorally active. This study was concerned with how to prepare computerized learning environments to help the ineffective learners become effective self-regulated learners. This study investigated the effects of two different computer-assisted instructional (CAI) environments and the effects of self-awareness of cognitive tempo styles on college students' self-regulated learning (SRL) skills and their academic achievement scores. MANOVA tests revealed that an intelligently adaptive CAI environment was significantly more effective on behavioral SRL skills than a totally learner-controlled CAI environment. This study suggests that educators and instructional designers invest their efforts in developing and utilizing CAI that serves as an intelligent partner to human cognition and that helps learners become self-regulated learners.

Theoretical Framework

Recently developed computer-assisted instruction (CAI) allows learners to have highly individualized interaction with the computerized instruction. Research studies, however, revealed that neither totally program-controlled CAI environments nor totally learner-controlled CAI environments provide high motivation toward the learning processes and high achievement outcomes [Steinberg, 1989]. Therefore, consideration should be given to designing CAI environments with appropriate instructional methods, which more intelligently interact with individual learners and guide them toward acquisition of required knowledge and skills in each step of learning processes.

Current computer authoring system technology enables instructional designers and developers to incorporate special constructivistic instructional methods such as cognitive apprenticeship into CAI environments [Lajoie & Lesgold, 1989]. Researchers and practitioners of the cognitive apprenticeship teaching method suggest that cognitive knowledge and skills can be taught by cognitive coaching strategies and learned better by *learning-through-guided experience* [Collins, Brown, & Newman, 1989]. When learning is completed, learners will increase learning responsibilities and shift expertise from the computerized coaching system. The process of learning responsibility and expertise shift can be observed by the utilization of self-regulated learning (SRL) skills: that is, metacognitively, motivationally, and behaviorally active involvement in their learning processes [Zimmerman, 1994].

Important for educators are the innovations of CAI environments implementing the cognitive apprenticeship method that helps the computerized instruction become more intelligently adaptive to learners. These innovative CAI learning environments may enable learners to learn in constructivistic ways exploring a rich information world, help them develop effective SRL skills and increase ownership of learning process, and lead them toward successful academic performance. This potential effectiveness of implementing the cognitive apprenticeship method in CAI environments has not been found from totally learner controlled CAI environments.

BEST COPY AVAILABLE

Research Design

Based on the theoretical framework, a study was conducted to compare the effectiveness of two different CAI environments on college students' acquisition of knowledge and performance in problem-solving situations. Seventy-five college students participated in the study. There were two independent variables: (a) CAI environments with two levels: an intelligently adaptive CAI environment and a totally learner-controlled CAI environment. (b) self-awareness of cognitive tempo styles: reflective or impulsive. There were four dependent variables: (a) self-evaluation levels, (b) self-efficacy levels, (c) self-learning activity levels, and (d) academic achievement scores. The instruments used in this study were (a) an adolescent-adult version of Matching Familiar Figure (MFF) test to rate the participants' cognitive tempo styles as impulsive or reflective [Kagan, 1981], (b) CAI programs, and (c) a computerized test with 15 questions. Among the 75 participants, 32 participants were defined as impulsive and 43 were reflective by the MFF test. Using a stratified random sampling method, participants in each cognitive tempo group were randomly, but proportionally, assigned to one of the two CAI environments. Five hours were provided for the self-paced learning with the CAI.

Results and Discussions

Two-way MANOVA revealed that, in the CAI environments, there was a significant difference in the college students' SRL skills due to the different instructional methods ($p < .0001$). Implementation of the intelligently adaptive coaching strategy of cognitive apprenticeship method was significantly more effective on encouraging the college students to exercise SRL skills than the totally learner-controlled method. The following univariate test on each variable showed that the self-learning activity levels were the most significant contributor to this significance, $F(1, 71) = 38.50$, $p < .0001$. That is, in the CAI environments, the college students who received the intelligently adaptive coaching method were significantly more behaviorally active ($M = 111.39$, $SD = 16.56$) than the college students who were allowed to have a total control over their learning processes ($M = 81.29$, $SD = 24.44$). There was no significant effects of self-awareness of cognitive tempo styles and no significant interactive effects between self-awareness of cognitive tempo styles and the different CAI environments.

The findings of this research study support Clark's long-run argument that computers are merely delivery tools [Clark, 1994]. The factor that influences learning is the instructional method. Effectiveness of CAI, especially in order to enhance learners' responsibilities in learning, depends on the effectiveness of instructional strategies employed in the CAI environment. This study proved that an intelligently adaptive CAI environment could help college students experience cognitive effects with the computer tools. In particular, the CAI environment that incorporated an intelligently adaptive "cognitive coach" encouraged the college students to employ SRL skills that helped them become self-responsible learners. This study suggests that educators and instructional designers invest their efforts in developing and utilizing CAI that serves as an intelligent partner to human cognition and that helps learners become self-regulated learners.

HYPERCLOCK : A CONCEPT OF A NEW NAVIGATIONAL TOOL BASED ON HYPER-G

Bin Cui
Institute for Information Processing and Computer Supported New Media (IICM)
Graz University of Technology
A-8010 Graz, Austria
bcui@iicm.edu

Abstract: Hyper-G is a second-generation hypermedia information system represented by the features including hierarchical structure, separate link database and so on. HyperClock, a new navigational tool, can exploit such features by developing a flexible and uniform user interface, upon which some information and relationship visualization techniques are developed. Using HyperClock can improve the performance of some hypermedia application issues such as navigation by integrating DAG structure, Local Map and History Map into one interface, and the "getting lost in hyperspace" problem can be solved in a new way.

1. HYPER-G AND HARMONY

Instead of a detailed and in-depth description of Hyper-G and its client Harmony [Maurer 96], only part of their features relevant to the approach in this paper are introduced briefly in following subsections.

1.1. STRUCTURED HYPERMEDIA AND ASSOCIATIVE HYPERLINKS

The Hyper-G Data Model contians structuring element named *Collection*, which is composite object that contains documents or other Collections. This definition leads to the concept of a *Collection Hierarchy*, on which two restrictions are applied :

- Every document or Collection (except for the Root Collection) must be a member of at least one Collection;
- The Collection Hierarchy must be cycle-free, that means, the hierarchy is *Directed Acyclic Graph* (DAG).

Hyper-G stores links in an own database. Links are bidirectional to guarantee the link consistency and are searchable in terms of type and keywords. Documents of any type can be linked with each other.

1.2. NAVIGATIONAL AIDS

Harmony has tightly coupled the Hyper-G's facilities described above to provide the following navigational aids :

- *Collection Browser* : provides intuitive hierarchical navigation through Hyper-G Collection structures;
- *Local Map* : visualization of relationships between object in terms of hyperlink or other attributes;
- *History Browser* : maintains a *history list*, in which each entry is time-stamped.

2. THE CONCEPT OF HYPERCLOCK

2.1. THE INFORMATION VISUALIZATION TECHNIQUE

HyperClock is designed to visualize a DAG structure so that a number of operations on the Hyper-G Collection structure such as navigating, searching can be carried out in an efficient way. From the geometrical point of view, the user interface of HyperClock is a circular plane consisting of a number of sectors where the center maps the current root of DAG and each sector maps a node. In accordance with Collection Hierarchy described in section 1, the concept of so-called *Sector Hierarchy* can be defined in a similiar way. In the case of "1 child

- to - n parents", the "child" is virtually duplicated n times at first, and then each one is mapped to the Subsector of its "parent". Due to the geometrical nature of the circular plane used by HyperClock interface, Sector Hierarchy is defined in a "circle" way :

- *(Sub)Sector* : the same as mathmatical definition. It can be thought of (sub)directory of file system;
- *Circle* : connects all the nodes with the same height in DAG and limits the sectors accordingly;
- *Center* : the root of the current Collection structure of DAG.

In addition to the basic components of HyperClock interface described above, just like pointers of a clock, the other components should also be defined to make HyperClock work :

- *Sector label* : identifies a particular document or Collection;
- *Flag* : marks the location of a particular document or Collection and can be assigned with some value;
- *Dot* : a point located along with the outmost Circle that represents a particular document or Collection. Dots are displayed only if relationships among documents or Collections should be visualized.

2.2. THE RELATIONSHIP VISUALIZATION TECHNIQUES

Based to the information visualization technique used in the HyperClock interface, the relationships among documents or Collections can be represented in various ways to accommodate different needs in some hypermedia application issues such as navigation, and the relationship visualization techniques described bellow can be applied in any combination when needed.

a) Simple connection : segments between related documents or Collections represented by Dots are drawn regardless of direction and other features of the relationship to get an intuitive description.
b) Central connection : in the case of "m - to - 1 - to - n" relationships, the one Dot is placed at the center, all m segments connecting Dots and the center are drawn in one color, all n segments in another color.
c) Inside connection : assum that the relationship between Dots d1 and d2 should be displayed, the visualization carries out in three steps, (1) a value "d-r" along with the radius is caculated automatically according to the amount of relationships to be visualized; (2) segements along with the radius toward the center of length of "d-r" are drawn from d1 and d2 , ending at d11 and d22, respectively; (3) drawing the arc connecting d11 and d22 along with the circle. If the relationship is directed, color can be used to differentiate the incoming "d-r"-segment from the outgoing one.
d) Outside connection : same as c) except that segments along with the radius are drawn away from the center.

3. THE NEW NAVIGATION PARADIGM

3.1. "CIRCLE" INSTEAD OF "LINE"

Different from using "Line"-style interfaces, users are always presented with a sense of global context of certain Colloection with HyperClock. Furthermore, a set of functions are supported in a uniform way regardless of the location in the DAG structure. Relationships among objects in the database can be visualized efficiently in different way to meet different needs.

3.2. "MAP" INSTEAD OF "LIST"

The advantage of "Map" over "List" is that user can jump to some location directly without referring to the "List". While the *History List* can not always provide a clear guide, a *History Map* might help the user decide where to go to. By applying the HyperClock to search issue, the search result is mapped onto HyperClock interface directly to provide a so-called *Result Map*, with which the user can immediately select some collections to refine his search.

tdakin@uwic.ac.uk and ejones@ uwic.ac.uk

Abstract: LINES (Learning and Information support Networks in Europe for SOCRATES) is a World Wide Web system to support student and staff exchange throughout Europe. LINES is being developed by a transnational partnership representing the UK, Sweden, Belgium, France, Denmark and Greece and provides facilities to support the whole life cycle of transnational exchange from planning and setting up the exchange, allocating funding, monitoring student achievement to the provision of statistical analyses for institutional, national and European administators. The system supports the European Credit Transfer System and provides on-line Open and Distance Learning support. LINES has been funded by DGXIII of the European Commission as part of the IVth Framework Telematics Applications Programme.

Introduction

Every year a vast number of higher education staff and students participate in European Commission (EC) funded transnational exchange programmes, e.g. ERASMUS. Under ERASMUS transnational exchange grew exponentially: in 1987/88 there were 300 and in 1995/96 170,000 student exchanges within single or multiple exchange networks known as Inter-University Cooperation Programmes (ICPs) each ICP administered separately by a coordinator closely related to the course. In 1997 ERASMUS becomes part of SOCRATES and multiple ICPs within institutions will be rationalised into a single Institutional Contract to give each institution more administrative control through an officer much less closely related to individual courses. Through SOCRATES the EC is strongly promoting the European Credit Transfer System (ECTS) with the aim of giving full credit for transnational study in the home institution. Within SOCRATES transnational exchange is set to grow to a target population of 4,000 institutions, 500,000 staff and 7,500,000 students and thus the scene is set for a management information system which can support the SOCRATES Institutional Contract. LINES is such a system and aims to enhance the transnational experience by supporting the whole life cycle of transnational staff and student exchange from planning and setting up the exchange, allocating funding, monitoring achievement, to providing institutional, national and European statistics.

LINES: Learning and Information support Networks in Europe for SOCRATES

LINES (Learning and Information support Networks in Europe for Socrates) has a total budget of 1 million ECU from DGXIII under the IVth Framework Telematics Applications Programme (one of the largest and most important EC initiatives the strategic purpose of which is to coordinate European actions in communications technology to provide effective competition to the USA and Japan). Against this evolving and generally supportive background a growing number of individuals are engaged in facilitating exchanges or undergoing the experience at first hand. LINES has its origins in the experiences of partners in the Brussels-based BUSINET organisation of some 80 European business schools. LINES is led by the University of Wales Institute, Cardiff (UK) and Växjo University (Sweden) with three other partners: BUSINET who will organise the system demonstration in about 50 Institutions; Artisan Konsult (Sweden) who are determining user needs; O2 Technology (France) - an object-oriented database manufacturer.

LINES aims to use new but established technologies to dynamically support various client groups: staff attempting to establish exchange agreements with other colleges; students and staff contemplating exchange; tutors and administrators keeping track of exchange students, funding and qualifications through ECTS; national and European coordinators seeking summary data. LINES holistically underpins the SOCRATES Institutional Contract and is a generic system covering most institutional needs that is, wherever possible, able to utilise and integrate existing independent systems.

Exponential growth of the total number of students and institutions participating in ERASMUS has brought a concomitant increase in the difficulties of obtaining relevant course information on which to base decisions about appropriate exchanges, e.g. inter-institutional module equivalences - is 'Introduction to Database' in University of Wales Institute, Cardiff equivalent to the same level module 'Database Structure' at Växjo University and would students be able to equate the curricular experience whilst enhancing their cultural experience? ECTS provides a format for making curricula more transparent and is strongly promoted by the EC for this reason. LINES is based on ECTS to enable inter-institutional mapping of modules and programmes.

Maintaining up-to-date documentation in a pan-European context is problematic. The LINES object-oriented database uses dynamic data acquisition techniques to deliver current information on potential exchanges. LINES uses a federated/distributed database in which each institution has responsibility for the maintenance of its own data. LINES is a dynamic information resource with course and module details as well as information on the exchange institute, its geographic region and culture to help preparation for exchange.

LINES also lays the foundation for integrating Open and Distance Learning (ODL) to support ECTS. One of the common difficulties encountered in exchanges is the dichotomy between the potential benefits for the student and the results of mismatch in study programmes that lead to study deficits on return home. On-line ODL is the favoured solution to overcoming curricula mismatches, LINES lays the foundations for a very large ODL network across Europe. Linked to the module database four ODL packages have been prepared to demonstrate the framework although LINES has concentrated not on ODL production but on collaborative ODL development and delivery issues in a pan-European context.

An α-version of the LINES system has been produced for evaluation from January 1997 at four sites (UK, Sweden, Denmark and Greece) the results of which will inform the development of a β-version for July 1997. The β-version will be used to administer SOCRATES exchanges between July and December 1997 at 15 sites that have been selected for their competence in developing computer systems. The project is scheduled to expand to around 50 sites during the demonstration phase in 1998.

Conclusion

Against a background of projected and rapid increases in the number of staff and student transnational exchanges and their mode of administration, LINES is a powerful administrative tool to support participating administrators, academics and students within SOCRATES. Functionally LINES uses dynamic data acquisition techniques to provide a single coherent networked system which enables tracking of individual mobility and supports: student registration; records of achievement; modular support; study programmes; distance and open learning; financial tracking; statistical reporting for exchange administrators at a national and European level. LINES has in-built generic features that facilitate the support of a wide range of functions within the overall umbrella of lifelong learning and could support other credit-based exchange programmes.

Acknowledgments

The authors thank DGXIII for their financial support of this project under IVth Framework Telematics Application Programme. The authors also acknowledge fully the work of all LINES Project Partners: Växjo University, Växjo, Sweden (Lars-Eric Ljung); Artisan Konsult, Växjo, Sweden (Soren Stromberg); BUSINET, Brussels, Belgium (Ingace Ingelaere) and O2 Technology, France (C. The Power of Animation in Visualizing Mathematics

TILAK DE ALWIS
Department of Mathematics
Southeastern Louisiana University, Hammond, LA 70402, USA
E-mail: fmat1117@selu.edu

Abstract: The impact of computer algebra systems (CAS) combined with powerful computers on the mathematics curriculum are enormous. The mathematics instructors are gradually changing their teaching techniques because of these technologies. One can use a CAS such as *Mathematica* to create animations to successfully teach certain mathematical topics which require visualization. In this paper, we will show how to use *Mathematica* to create animations of classical Greek curves such as cycloid, astroid, cardioid and deltoid.

Introduction

Using a CAS such as *Mathematica*, mathematics instructors can create animations to effectively deliver their message. There is some amount of research supporting the effectiveness of animations in computer based instruction. For example, there are studies comparing learning conditions of text only, text and graphics, and, text and animations [Baek & Layne 1988]. It shows that the adults in the study were able to score higher in the animation condition than either text or graphics. For other encouraging studies supporting the use of animation, the reader is urged to refer to [Mayton, 1991].

In this paper, we will show how to use *Mathematica* to create several mathematical animations to understand the classical Greek curves such as, cycloid and the astroid. For the interested reader, some good references on *Mathematica* are [Wagon, 1991] and [Wolfram, 1991]. What we have used is *Mathematica* version 2.0 on a Power Macintosh platform running at a clock speed of 90 MHz.

The Cycloid and the Astroid

The cycloid and astroid belong to a large family of curves known as the classical Greek curves. Other such include cardioid, cissoid, conchoid, deltoid, nephroid, strophoid and trochoid. Most of these curves can be generated by considering the loci of suitable geometric objects. Therefore, one of the best ways to visualize some of these classical Greek curves is by making animations. In the treatment below, we will only consider the cycloid and astroids. For further details on these and other classical Greek curves, the reader may refer to [Burton 1991], [Eves 1992] and [Yates 1952].

(a) The Cycloid

Consider a circle rolling along a straight line without slipping. Then the path of a fixed point on the circumference of the circle is called a cycloid. For example, a mud patch on the edge of a rolling tire traces a cycloid. One can effectively use a *Mathematica* animation to visualize the shape of this curve, as given by the following program.

Program 1

```
a = 1;
Do [ Show [ Graphics [ { Line [ { { - a  - 1, 0 }, { 4a*Pi + 1, 0 } } ], { Thickness[ 1/180 ],
Line [ { { a*t, a }, { a*t - a*Sin[ t ], a - a*Cos[ t ] } } ] }, { RGBColor [ 1, 0, 0 ], Thickness [ 1 / 250 ],
Circle [ { a*t, a }, a ] }, Table [ { RGBColor [ 0, 0, 1 ], PointSize [ 1 / 160 ], Point [ { a*u - a*Sin[ u ],
a - a*Cos [ u ] } ] }, { u, 0, t, 4Pi / 40 } ] } ], PlotRange -> { { - a - 1, 4a*Pi }, { - 0.2, 2a + 1 } },
AspectRatio -> Automatic ], { t, 0, 4Pi, 4Pi / 40 } ]
```

When the above animation is run, one can notice a circle rolling along a straight line. The animation creates footprints of a fixed point on the circumference of the circle. In this way the beginner can easily visualize how the cycloids are generated. Some frames of the animation are given below in [Fig. 1].

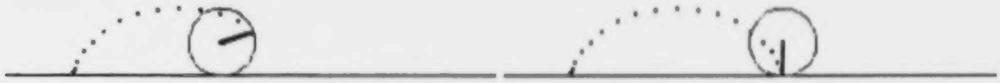

Figure 1: An animation of a cycloid

It must be noted that an arbitrary point (x, y) on the cycloid can be parametrized by the equations $x = a(t - sin\, t)$ and $y = a(1 - cos\, t)$. Here, a represents the radius of the rolling circle, while t is a real parameter. One can use this parametrization to verify several mathematical properties of the cycloid. The cycloid is in fact, quite rich in history. Famous mathematicians such as Galileo (1599), and Roberval (1634), and architects such as Sir Christopher Wren (1658) have discovered several mathematical properties of the cycloid ([Yates 1952]). The cycloid also provides the solution to the famous Brachistochrone problem, first proposed by Jean Bernoulli in 1696 ([Burton 1991], [Eves 1992] and [Yates 1952]). Because of its elegant properties, and the controversies it has caused among eminent mathematicians, sometimes the cycloid has been called the Helen of Geometry.

(b) The Astroid

This is another classical Greek curve that can be generated by methods similar to that of a cycloid. Consider a small circle, rolling without slipping inside of another bigger circle with radius four times as large. Then the path of a fixed point on the circumference of the small circle is called an astroid. Unlike the cycloid, the astroid has four cusps. For this reason, sometimes it is called the tetracuspid. The following *Mathematica* programs creates an animation to generate the astroid.

Program 2

```
Do [ Show [ Graphics [ { Circle [ { 0, 0 }, 1 ], Circle [ {3 / 4 Sin [ t ], - 3 / 4 Cos [ t ] }, 1 / 4 ],
    { RGBColor [ 1, 0, 0 ], PointSize [ 1 / 50 ], Table [ Point [ { ( 3Sin [ s ] - Sin [ 3s ] ) / 4,
    - ( 3 Cos [ s ] + Cos [ 3 s ] ) / 4 } ], { s, 0, t, 2Pi / 40 } ] } } ], AspectRatio -> Automatic ],
    { t, 0, 2Pi, 2Pi / 40 } ]
```

Computerized African Language Learning (CALL)
Interactive, adaptive, dynamically expandable and using multimedia

Gideon de V de Kock (csagdk@upe.ac.za) and Marinda Taljaard (csamt@upe.ac.za)
Department of Computer Science & Information Systems, University of Port Elizabeth, Port Elizabeth. South Africa.

Abstract

The paper reports on a computer assisted language learning title to teach an introductory course in Xhosa, a native African language spoken by most of the black citizens of the Eastern Cape Province of South Africa. The course is aimed at non-Xhosa speakers. The course interact with the user, adapts to some of his preferences and displays Xhosa sentences/phrases and allows the user to listen to its pronunciation. An audit trail is kept of all the details of the user's interactions and performance. The system can be expanded by changing the database consisting of the words, phrases and wave files.

1. Introduction

Xhosa is a native African language spoken by about 10 million black South Africans, predominantly from the Eastern Cape Province of South Africa. The University of Port Elizabeth (UPE) is the largest of the five Universities serving this region. Xhosa is one of the eleven official languages in the new South Africa, and one of the three languages extensively used in the Eastern Cape, the others being English and Afrikaans. The latter two languages are mainly spoken by people of European descent who has no or very little knowledge of the Xhosa language and culture.

In order to improve relations at all levels of society and business, it is important that as many as possible non-Xhosa speaking people, in the Eastern Cape at least, obtain a reasonable reading and understanding proficiency of Xhosa. This need motivated the research for and development of this multimedia-based introductory Xhosa language course.

In the design the ideas expressed by Eve Wilson [Wilson 94] has been very helpful. Since it is considered that interaction with a foreign language in text form represents input from which learners can discover grammatical regularities more easily than in its spoken form [Carrol 86], interaction is mainly through typed text, but learners do have the choice of listening to the Xhosa pronunciation. The course was developed using the QUEST authoring system supplemented with a number of DLL's written by one of the authors.

This course is aimed at non-Xhosa speakers with a good reading proficiency in and comprehension of English, and no or very little knowledge of the Xhosa language. Furthermore, little knowledge of computers is required. At UPE this CALL course will also be used to supplement the conventional course in providing unlimited drill and practice.

Objectives :

To facilitate the learning of Xhosa in order to read, understand and write it, with less emphasis on speaking the language; to allow for updating the learning material without recompiling the title; to dynamically adapt to the preferences and the level of the student.

2 Structure of the Course

The course structure is based on an introductory Xhosa course which has been offered by the Department of African Languages at UPE. This course was previously implemented as a CALL by Dr R M J Britz of this Department, but it had severe limitations [Britz 88]. The problems experienced however, were valuable in the design and implementation of the new multimedia-based course. It was, for example, experienced that learners had extreme difficulty with the complex grammar, spelling and the pronunciation of the Xhosa language.

After the login/registration screens, the learner is presented with a content page displaying all twenty units of the course. Unit one deals with the infinitive of the verb. Units 2 to 9 covers the different classes of nouns. Unit 10 is a revision test/tutorial on units 1 to 9. Units 11 to 19 covers with increasing complexity the construction of sentences and deals with the declinations and inflections of verbs and nouns. Unit 20 is a revision test/tutorial on units 11 to 19.

In general a unit is structured in pages (frames) as follows:

- Examples are given in text, followed by a few questions directing the student to discover the specific knowledge.
- Feedback on the answers of the questions is given followed by a summary of the theory/knowledge and any exceptions, if applicable.
- A number of questions is given relating to the specific knowledge followed by feedback.
- Browsing randomly through the examples pertaining to the unit.
- A test on the unit which is corrected with feedback. Once the test is completed the student can request his statistics on the test, redo the unit/test or if the test was passed, continue with the next unit.

3 Learner Model

When a learner enrolls for the course he chooses a usercode and password, and then supplies his full name, the name he is called by, age, gender, level of education, English reading proficiency, knowledge of Xhosa, interest in the subject and computer familiarity. The Last unit number passed and for each test the number of attempts, the highest and average score, learner's preferences for voice and automatic speech is updated dynamically.

For each learner an *audit trail* consisting of entry date and time stamp, number of voice clippings listened to for each frame, score, questions and answers for each test, changes in the learner's preferences for voice and automatic speech, details on each interaction with a scenario, details of each consultation of the dictionary are stored.

Apart from the test on each unit, the two revision tests mainly serves to assess the learner. The audit trail contains the detailed information on the scores of all the tests and an analysis of these will lead to an improved assessment in future. A more complex learner model on the lines of the ideas reported by Shute [Shute 94], is being designed, which should improve the adaptability of the system.

4 Didactic Model

Since most users will have little knowledge of the language, it is important to use didactic models which will aid the learning process. Throughout the course, the Xhosa phrases/sentences and its English meanings are displayed, and the learner may repeatedly listen to the pronunciation of the Xhosa displayed by merely clicking on it.

The learner is also guided through the units in that he must pass the test in each unit in order to continue with the next. Although the learner can see all the units in the contents page, he can only access the units already passed and the next one. Once a unit has been passed he can repeat any frame of the unit through a little unit index for revision and drill purposes. Since examples, drill and test questions are randomly selected, repetition of frames is not boring.

The approach thus far described, is mainly instructivistic. The independent browsing through the scenarios and dictionary represent a constructivist approach.

5 System Evaluation

The system forces the learner to evaluate the system at regular intervals after successfully completing predefined sections of the course. The learner is automatically taken to a specific evaluation page for the section where he must answer multiple choice evaluation questions before he can continue! Furthermore, users are invited from the contents page to complete an evaluation form represented as a page consisting of a number of multiple choice questions [Agnew et al. 96] [Dutt et al. 95]. Answers to the evaluation questionnaires are also recorded in the audit trail.

The course supervisor is able to register students, set parameters, print various reports and change some of a student's data. Sophisticated methods and programs will have to be developed to analyze the audit trails statistically in order to evaluate each component of the course, to establish which learning material is difficult for the learners and to determine areas where possible remedial units may be required.

6 Scenarios and Dictionary

Scenarios evoke curiosity and stimulate learning [Lepper 1993]. Therefore, a number of scenarios are available depicting some everyday scene, e.g. a typical kitchen where a mother is busy preparing a meal, also showing children and pets. By clicking on any object a typical Xhosa sentence or phrase will appear and the learner hears the associated speech. It could also trigger a small animation to depict some action. This approach will allow the learner to discover names of objects and sentences in context of the scene.

In view of the importance of on-line dictionaries and glossaries ([Aust et al. 93] and [Roby 94]), an on-line bilingual dictionary is in progress. It will contain all words used in the course and with each word the typical expressions and phrases using the word, meanings and possible synonyms. The learner must also be able to listen to these Xhosa phrases/sentences. In working through the units he must be able to select a word and link to its entry in the dictionary and/or have the option to browse the dictionary to see 'adjacent' or closely related words.

'Techknowledgy' Transfer and CMC in Higher Education in Australia

A. F. Dean
Information and Communication Technology Department
University of Wollongong
Australia
tony_dean@uow.edu.au

Abstract:- This paper reports on the use of computer mediated communication (CMC) in classes for fourth year and masters students at the University of Wollongong in Australia. Each year the CMC component of the subject has been orchestrated in a different fashion to enable the role of the moderator to be examined. Importantly, the appropriated notion of 'technology transfer', is examined in relation to the CMC. Students benefit from the opportunity to interact with each other, the educator and the guests (experts) invited to participate in the 'event'. Preparation is critical to the optimal use of CMC in higher education, so transfer of knowledge about the operational aspects of the software as well as the affective aspects of CMC has to be considered before the CMC is conducted. The approach recommended mirrors the literature on technology transfer that calls for greater dissemination of the knowledge 'behind' and embedded within the technology and its use.

Technology transfer

Technology transfer is a concept that is often found in the literature relating to the implementation of 'high-technology' by under-developed countries or it may relate to the uptake of new technology by an organisation. It has been argued that the provision of hardware and/or software without the background knowledge that led to its development and which is arguably crucial to its maintenance is only going part of the way to 'transfer' the technology to the recipient. The following excerpt [DIST, 1994] is germane to the issue

> Technical progress cannot be exclusively embodied in capital good, because it consists of a part 'embodied' in people, institutions and societies. Hence as Arrow (1962) points out, 'learning by doing or using' is an important factor in the uptake of new technology.
>
> Technology uptake refers to far more than simple introduction of new machinery onto the factory floor or into the office and much more than the simple transfer of technical information. Of greater importance is the transfer of know-how (that is, accumulated learning-by-doing skills) which is extremely firm-specific in nature. This is because internal reorganisation of both production and management processes, and upgrading of skills, may be essential to capturing economic value from investment in new technology (OECD 1988). [DIST, 1994. p.23]

In this paper the concept of technology transfer is appropriated and applied to the use of computer mediated communication (CMC) to see if the greater provision of information about the non-technical (social) aspects of computer mediated conferences can help to deliver greater benefits to students. The learning by doing, referred to by Arrow, may be enhanced if the students, as 'receivers' of the new technology, have been well prepared. Through increased understanding, the students' own, 'internal reorganisation' may well be promoted in the form of improved learning - a change to the cognitive strucutres? The conferences in question have been run during 1995 and 1996 and form an integral part of the students' studies from both content and experiential perspective.

Computer Mediated Communication/Conference (CMC)

From experience with CMC the author has formulated the notion that the use of this technology in education requires detailed preparation that attends to both the technical aspects, such as the use of software and hardware, as well as to the social components. The neologism 'techknowledgy' is therefore introduced to emphasise the knowledge component of technology whether it be codified or tacit in nature. Within a computer mediated conference students have a need to use email and screen editor software and, in the cases under examination, they also needed to learn how to use a 'listserver' i.e. the conference software. In order to research the notion of 'techknowledgy' transfer the author has incorporated conferences into his subjects and has experimented with different emphases over time.

The literature on CMC has become expansive and contains a number of salient lessons for educators wishing to use CMC in higher education. Now recognised as a medium in its own right, CMC cannot be taken for granted when it is used in education. Students need to be aware of the medium to use it effectively and so providing them with information (training) about the 'mechanical' aspects of accessing a conference and making contributions is only one part of the educators' task. In this author's opinion it is also necessary to bring lessons from the literature to the students so that they can be forewarned about the CMC and how others have felt during their own experience. To this end an appropriation of the notion of technology transfer referred to above, is advocated, with the intention of advising the students about the volume of mail they will receive and the effect that that volume might have on them; they are also told about the use of idiomatic language and the need for it to be accompanied with some form of 'decoding' so that other participants can distill their meaning; I suggest to them that their own learning will be opimised if they become involved in threads of discussion, rather than remain as 'lurkers'; comment on the style of the medium and its impact on dialogue, is provided, in particular the tendency for the text responses to become truncated, terse and unlike other forms of expression and media used in discourse; and I advise the students about the issues of stereotyping other contributors. These are among the topics that I believe need to be addressed in advance of the formal CMC component of a subject of study if the environment of CMC is to become 'familiar' and the learning maximised. Interestingly, not all of these relate to the actual content, nor its meaning, for they go outside the dialogue to the contextual arena. It is my contention that the students will gain most from the experience if they are able to immerse themselves in the discussions, though not always by dominating the discourse with their contributions. Immersion here refers to their informed observation of the progress of the CMC in terms of both its content and its 'feel'. I am not suggesting, however, that we look for ways to 'can' such a feel for mass production, for the tone and texture of any CMC depends on its participants. The 'feel' of the CMC is nonetheless an area for further examination and the current (ongoing) study is attempting to do so. The CMC literature reports instances of conference goers feeling threatened, marginalised and inadequate and due attention is being paid to these as being some indicators of comfort. The way in which the participants 'relate' to the conference is likely to be a measure of their degree of comfort and so the emphasis has been on collaboration and non-competition.

The Conferences

In both the conferences held to date the students (fourth year and masters levels) have been given instruction in how to use email ('elm'), a screen editor for use on a UNIX system ('jove') and how to subscribe to, and then to use, a listserv ('majordomo'). The 1995 students were given a cursory introduction to the concept of a CMC but no attempt was made to inform them of the various findings in the literature regarding the implications of the use of such a medium. No 'netiquette' was covered nor were anecdotes provided about what other educators and students had found in their own use of CMC. In short the 1995 groups were introduced through a primarily technical training approach. The 1996 students' instruction included all such information and, in addition, some discussion during the CMC was focused on the issues of the 'look and feel' of the conference so that the participants were required to reflect on how they were reacting to the CMC at those times.

In both years a number of guests, academics and professionals, have been invited to the CMC with the purpose of being advisors to, and resources for, the students. The students form groups to research and then compose 'journals' which are the major assessable item in the subject being studied. The journals are broken into 'chapters' which are the responsibility of a single student and which collectively are brought together (as the journal) to answer the groups' question. The students receive a common score for their journals' 'editorial consistency' and they receive an individual score for their own chapter which is a sub-set of the journals' topic.

Threads of discussion in the conferences were related to the students' journals and to the subject which examined

- the 'information society'
- the impact of information and communication technology (IT) on society especially in regard to the skill and knowledge required to be a highly valued member of the work force - a knowledge worker, and
- the manner in which IT could be used to facilitate higher education for the knowledge worker group

Data from the Computer Mediated Conferences

The students in the two CMC conferences, conducted to date have been surveyed for their opinions and observations about the way in which the CMCs have been operated and the way in which they have responded. Their comments have been reported elsewhere [Dean, 1997] and here, due to space constraints, the crucial findings only are presented.

Students were asked to complete summative questionnaires, of the CMC, at the completion of the subject, with due regard for anonymity. The selected data presented here were collated from 73 students' responses received over the two years as follows:-

1995	undergraduates	18 responses with 6 female and 12 males.
1995	postgraduates	24 responses with 7 females and 16 males (1 wasn't indicated).
1996	undergraduates	20 responses with 11 females and 9 males.
1996	postgraduates	11 responses with 3 females and 8 males.

The questionnaires were almost the same for the two years (the 1995 questionnaire had 35 questions rising to 36 in 1996). The majority of the questions were closed and used Likert-type scales with five categories, other questions were open and elicited answers in either numeric or prosaic form. The responses to open questions have been tabulated and categorised subjectively on the basis of their similarities and/or differences. A few questions were nominal and asked for one of the proffered choices to be selected.

Being exploratory studies the author expected that the students would have responded differently over the two years. This they did though not for the reasons that might have been foreseen. There were a number of variables that may have come into play during the CMCs including the participation of different guests and students, different journal topics under study (for 1995 and 1996) and the different amount of pre-exposure to the use and role of CMC in higher education. No attempt was made to control these variables and so caution is warranted in any further extrapolation from the results. Unless otherwise stated all the ratings or scores here were from 5 point Likert-type scales, 1 to 5 with 5 being highest.

In general the students have endorsed the use of CMC in their studies with an overall average of 3.48. However the 1995 group average of 3.64 exceeded that for 1996 at 3.26 indicating that factors other than the introductory preparation were at play.

At 3.81, for the two years, the students view positively the future role of CMC in higher education and they averaged 3.84 in their view of the capacity of CMC to further their knowledge as a part of formal study. With an average of 3.77 they seemed to believe that CMC may also have a part to play in their professional employment and/or development. An important follow-on from this realisation is the finding that, with an average score of 4.36, they have come away from the CMC believing that it will be very advantageous in the event that they are involved in a similar forum again - in other words the learning by doing seems to have had a resoundingly positive outcome. This finding would seem to support the contention that the technology has been 'transferred', in operational terms at least. The students' rating of the difference in their self-assessed knowledge of the CMC environment before (3.33) and after (4.18) the CMC was also an indicator that a good deal of learning had occurred. What is still an unknown, in the sense of this paper, is whether the argument in favour of the detailed exposure of students to the CMC literature as a part of their preparation can be sustained on the basis of the students' evaluation of the CMC. The CMC for 1997 has been restructured within the subject so that the students will have a two week 'trial run' of the CMC software (and the environment) before they launch into the real thing with the invited guests. This will hopefully point more conclusively to the role of such a preparation in 'transferring' the technology to the students.

The research in progress now moves onto the next stage which will see the students given the same full introduction as in 1996 but which will this time be accompanied by changes to the way in which the conference is conducted [1]. The conferences so far have been unmoderated with the author taking a back-seat role in the discussions though he has been active in the operational aspects of the conferences. In 1997 this will change so that the moderator role will be more pronounced. From what the students have had to say in their responses this particular change will be warranted and timely. The extra question included in the 1996 survey asked students what role the moderator should play. The 29 replies centred around 'editor' (11) and 'guide/facilitator' (10) though 1 said there was no need for a moderator and 5 suggested the role be confined to administration. From the many comments received the 'editor' should attend to tasks such as providing summaries and/or commentary;

filtering contributions and providing censorship and providing thread control when the conference has become fragmented. In a similar vogue the 'guide' was to lead topics, encourage participation, facilitate discussion, and provide email and technique training. When the reported 'worst three aspects' of the conferences are examined it is easy to see why the students believe an active moderator is needed - the 'volume of email' rated as the main culprit with 'amount of irrelevant information' coming second and 'time consumption' being the third area for complaint. On the other side of the coin students reported the 'best three features' - led by 'access to the international guests and their expertise', followed by 'access to a wide range of people for ideas' and then 'collaborative group work'. All six would seem to be likely beneficiaries of improved control within the conferences and so the change to the moderator role will be appropriate, timely and relevant to the ongoing research of the notion of 'techknowledgy' transfer.

Another interesting result was the identical score (4.1) from both years in relation to the 'promotion of the collaborative ideals involved in the CMC' which seems to verify the students' beliefs that the CMC experience has merit. It also seems to suggest that the students' experience has not suffered from the differences in provision of information outlined earlier. This needs to be followed in the research especially in terms of the relationship to the 'transfer' notion at issue in this paper.

The students estimation of 'CMC as an integral part of learning in future higher education' scored 3.74 and 3.86 for 1995 and 1996 respectively which is encouraging to this researcher given the amount of time and effort that is spent in organising and conducting such events. Similarly they scored 3.87 and 3.69 for 1995 and 1996 respectively when asked about the 'capacity of CMC conferences to further their knowledge as a part of their professional employment'. This also has a related importance in view of the fact that the students are all likely to become knowledge workers [2] as a result of their studies. Such workers are faced with the challenge of constantly updating their skill and knowledge bases and it may well be that they turn to CMC as a medium to provide such updates. In this sense the CMC has also played a vital role in informing their current skill and knowledge bases which was one of the essential reasons for undertaking the conferences in the first instance.

This paper has introduced the notion of techknowledgy transfer and has related it to the ongoing research of computer mediated conferences in higher education. It has been argued that there are crucial non-technical components to the medium that students should be introduced to in preparation for the advantageous use of this medium as a conduit for learning. The research has not been conclusive and is open ended as to the likely outcomes. However, if technology is seen to be 'disembodied intelligence' then it must have a non-technical manifestation which in the mind of the author is an area in need of further examination. It would also seem that the notion of technology transfer in its more usual place of study would do well to consider the cultural and contextual facets if greater success, than in the past, is to be had. CMC has potentials for assisting learning but like so much of our modern technology there is still much to be understood.

Footnotes

[1] The CMC conferences are run in the first session of our university calendar and last four weeks. Any reader wishing to observe, or participate in, the conferences can contact the author via the email address at the start of this paper. Classes would also be welcome.

[2] Readers are directed to references such as Robert Reich's The Work of Nations and Peter Drucker's Post-Capitalist Society for further information about the knowledge worker in the modern labour force. In brief they are people, usually highly salaried and educated, who contribute to their organisation by virtue of their intellectual capabilities. Adding value to information and creating new knowledge are fundamental to their performance.

iDEANet - An Exploration of 'Poly-Media':- the Potential of Compressed Video Television in Distance Education.

A. F. Dean
Information And Communication Technology Department
University of Wollongong, Australia
tony_dean@uow.edu.au

Abstract: This paper draws on path breaking experimental work conducted by the author which combines broadcast television with computing, and video and audio conferencing. The paper takes a 'what if' approach to show that this is a low-cost alternative for interactive distance education. The suggested configurations can be replete with high-technology aides or can be streamlined to suit the purpose of the educational endeavour and scaled back, where necessary, to match the existing information and communication infrastructure. The paper will draw on the original 'poly-media' configuration trial and the presentation, which is intended to be interactive and collaborative, will consider further hybrid application of the approach.

In November 1991 the author conducted a trial broadcast that brought together the technologies of television, video and audio conferencing and computing. The idea was to investigate the mix of these technologies to see if, firstly, the experiment would work and then, secondly, to consider the ramifications of success for the application of the approach to distance education. The first element was achieved with the yardstick for success being the decipherable reception of the signal by people in their own homes. Having proven that the technology was technically feasible the task to consider further application in distance education has been ongoing, hampered to this day by a lack of funding, interest and commitment. This paper then is a condensed attempt to re-ignite interest in the confluence of the technologies, used in the experiment, with a view to promoting it as a low-cost alternative for distance education delivery in both developed and developing nations. A fuller treatment can be found in another paper. [Dean 1996]

There are over 760,000,000 television (TV) sets in the world, many of which are used communally to overcome local deficiencies in finance or infrastructure. In more prosperous nations, ownership of TV sets is the norm for individual households with multiple sets often being purchased. One great benefit of TV is that people do not have to travel to be able to receive the transmitted broadcast signal. This is not the case with video conferences which are narrow-cast to the participants at, generally, fixed locations. In countries where video conference technology has been introduced to the delivery of distance education students are required to converge on a common place to be able to take place in the discourse. Similarly audio conferences are narrow-cast as well and so long as students have access to a telephone they can access such activities. Broadcast TV is expensive to produce but video and audio conferences are not, at least not by comparison, but they can hardly accommodate the vast numbers that regularly watch TV (in any transmission format).

The experimental broadcast sought to combine as many of the benefits of the respective technologies as was possible so that the resultant hybrid, which I have dubbed 'CVTV' - (compressed video TV) - would be an affordable alternative to the other available media, which tend to be fixed purpose. To this mix I also added computing technology so that the trial broadcast could simulate a lecture in higher education, with as many learning support devices on show as was possible for the 30 minute, specially approved, broadcast. This overall marriage of technologies I now refer to as a 'poly-media' approach to distance education and it is my hope that the concept once developed to a fuller extent might become known as iDEANet signifying its cognitive and network orientation. However, the naming conventions are secondary to the educative potential of the concept and to its realisation I now return.

CVTV - Trial Broadcast

The trial not only proved that the signal from a video conference studio could be redirected via terrestrial lines to a broadcast TV station but it also showed that the broadcast video conference pictures received in the viewers' homes was of equivalent standard to that received by the second video conference site (which was outside the viewing area). What this indicates is that, for a significantly reduced cost, an educational institution, in league with a broadcaster perhaps, could have an enormous audience for its 'product'. It is true that there would be a limit to the amount of interaction possible. The viewers (students) receive both picture and sound but by using a concurrent audio conference they only have an audio return channel. However, the trial showed that the six selected households in the viewing area could interact with the presenters in both video conference studios as well as with each other, via the same link. Students, as one suggestion, could therefore be 'rostered' over a session of teaching to represent their peers, asking questions and having input, and where feasible a telephone number could also be used to provide out of broadcast contact with the relevant academics or presenters. Again if the technological infrastructure allowed, the students could also be in contact with the studio(s) via (a)synchronous computer technology such as email, or real-time chat (e.g. MOOs or Internet Relay Chat) to have input whilst the broadcast is in progress. However, the permutations are numerous and will of course be subject to the local conditions and constraints. From the presenters point of view CVTV is a 'warts-and-all' approach to the use of the visual media, that is, if the transmission is to be in real-time. An alternative is to move to pre-taped editions with or without the expert in contact for the broadcast, which then allows for the tape recordings to be edited. In any event the signal can be taped in the home, or business, for later study so this variant allows for students to be present for the ephemeral broadcast or to tape it and then 'time-shift' to a time suitable to themselves.

There are too many aspects to this work to do justice to them all here. Suffice to say that if an institution could redirect video conference signals to a willing broadcaster then the cost of delivering the education to a 'mass' audience will be greatly reduced in comparison to the usual broadcast TV product. In the CVTV trial the potential viewing audience was about 500,000 people and the signal was delivered to their homes as a free-to-air broadcast. All up the costs for the trial, including costs of running the transmitter, hiring the necessary telecommunications lines, running the conference sites and so forth would have amounted to a figure under A$1000. That figure would have been much the same had the signal gone to a national broadcaster where the audience would have been, potentially, about 98% of the Australian population! Such economies must have a place in distance education, somewhere in the world, and this paper is an attempt to reach the people or institution(s) that can see the benefit of such a low cost alternative to current methods. I have been careful to keep in mind the level of technological sophistication present in countries around the world so that the ideas presented here can have applicability in widely varying circumstances. It is acknowledged that the solution presented herein requires substantial start up costs to acquire the video conference site(s) and to provide connectivity to a broadcaster. However, at the other end of the spectrum it is possible to utilise all the power and sophistication of the Internet and world wide web in CVTV presentations and to do so in real-time if that is desired. About the only thing that this approach is not suitable for is the presentation of very-high quality images (but then video conference signals are not meant to do so) or large amounts of rapid movement. An educator could however show three-dimensional objects, do free-hand drawing or painting, display computer images, use taped audio or video inputs, and hold a joint conference (as was the case in the trial) with a relevant guest or expert elsewhere in the world - in the latter case students would also have the opportunity to speak to such a person as well.

Broadcast TV in higher education has had a potted history. Many universities continue to use the technology and some are moving into this mode as pressures for places in their institutions increase. However, the relationship between broadcasters and higher education institutions has been uneven, to say the least, and this is in part because of the expectations that exist about the production quality of public broadcasts and broadcasters are very reluctant to hand over quality control to educationists. On the other hand educators have often reported their dissatisfaction with the results of the high cost TV production approach in which they have little control over content and 'flow'. Pedagogical technique seems to be the casualty in many cases and it is significant that pioneers of the use of TV in higher education, such as the Open University in the United Kingdom, have continued to reduce their reliance on this technology as a modality for the delivery of distance education. What is being suggested in this paper is an alternative to the 'slick' production values to which we have become accustomed over the years from watching broadcast TV. I have argued elsewhere [Dean 1996] that the 'expectations' of quality have not been rigourously tested in relation to students of higher education and the low-cost alternative may hold many promises that deserve to be investigated. Already the lower grade images of the video conference, accompanied with good quality audio, have been found to be acceptable to students, in university research, around the world. The CVTV hybrid seeks therefore to take that acceptance into a new arena by marrying the video conference signal with a broadcast capacity to reach larger student audiences.

Since the trial was run, the author has conducted further investigations of the approach outlined here. Not all of that work is able to be released, or published, as yet but is available under commercial, in-confidence, arrangements. The research in progress needs support to reach its full potential and to this end the current paper

solicits contact from interested parties. I hasten to add that this should not be construed as a shameless attempt at money grabbing, for the project, from its initiation, has had the greater good of the public at its core. I firmly believe that the CVTV concept has merit but to date I have had very little success in being the so called 'champion' of the technology in its educational setting and the progress of the project has been an object lesson in innovation theory. Somewhat frustrated, even daunted by the history till now, I have written this paper as yet another attempt to break through and I hope that what has been presented here will be enough to whet the appetite, or pique the interest, of someone who can help to bring this educative potential to fruition.

Abstract: In this paper we describe the instructional principles that guided the design procedure of a hypermedia learning environment we call "ISTOS" (the Greek word for "Web"). ISTOS has been primarily designed as a hypermedia environment for supporting instruction in the Computer Networking domain but the instructional prescriptions underlying its design could also be followed in other instances. We propose that the rationale introduced by Cognitive Flexibility Theory for advanced instruction in complex and ill structured domains can be extended and combined with the prescriptions of Elaboration Theory, Anchored Instruction and Cognitive Apprenticeship approach so that hypermedia environments for introductory and intermediate learning in complex domains can successfully be built. We also underline the notion that domain knowledge in an educational setting can be presented both in a highly and in an ill structured way, allowing the students to experience the expository and the knowledge inquiry way of learning.

1 The Instructional Approach of ISTOS

ISTOS has been designed as a hypermedia educational environment for supporting instruction in the Computer Networking domain and is currently being developed as an application on Wintel machines. Instruction in ISTOS is organized in a series of levels. At each level a working educational model is in use. A model used at a certain level is a further elaboration of the previous one. At each level of instruction student/users are guided to work through three distinct loci of activities: Analysis, Synthesis and Apprenticeship. Analysis and Synthesis are based on the instructional prescriptions of Cognitive Flexibility Theory [Spiro & Jehng 1990 ; Jacobson et al. 1995] while Apprenticeship offers an environment for cognitive apprenticeship combined with "free" thematic criss crossing [Jacobson et al. 1995].

Analysis

ISTOS begins instruction by presenting and analyzing to the students representative cases of real-life problem situations (i.e. problems of computer networks installations or upgrades) thus anchoring the abstract knowledge structures to concrete problems. What we seek is to create "an anchor or focus that generates interest and enables students to identify and define problems and to pay attention to their own perception and comprehension of these problems" [Bransford et al. 1990, p.123]. Cases are divided into smaller case-sections in order to better organize and handle the complexity of the presented material and they are delivered through a variety of media: text, audio, graphics, animation and video. A glossary facility is provided so that further information on newly introduced concepts is available by mouse-clicking on hyper-linked keywords. The glossary constitutes an educational design aspect based on the existence of highly structured knowledge, i.e. information that remains

BEST COPY AVAILABLE

unaltered and valid independently of the case under study (e.g. the concept of "network interface card", the concept of "synchronous transmission" etc.).
While browsing through cases, students are guided to study the "case-theme" commentary [Jacobson et al. 1995] that accompanies each case-section. These are comments that point out how a more abstract and structural characteristic of domain knowledge (a theme or concept) (e.g. the need for an efficient MAC protocol) applied in a specific way in the case studied (e.g. why Ethernet or Token-Ring protocol has been used). Fundamental in this design is the educational acceptance of the ill-structured characteristics of the domain, i.e. the introduction to the irregularity of application contexts.

Synthesis

In Synthesis student/users are guided to synthesize a more complex and in depth understanding of the presented material. A number of questions is provided and students are challenged to work out answers. ISTOS presents the questions accompanied by the relative themes and the case-sections where these themes appear and are commented. Students travel through hyperlinks to the case-sections to study the pointed out themes and formulate their answers. This is a thematic criss - crossing (TCC) activity similar to those applied in educational environments described by [Spiro & Jehng 1990] and [Jacobson et al. 1995]. Students engaged in this guided criss crossing are supposed to overcome the case - sensitiveness of concrete presentations and develop a more abstract, complex and multipathed understanding of the material presented.

Apprenticeship

Apprenticeship is a later phase of instruction where student/user plays the role of a Computer Networking expert challenged by domain problem situations and trying to formulate proper answers or solutions. The aim of Apprenticeship is to support both memory retention and deeper understanding by engaging student/users into knowledge inquiry activities. Students deal with "what" and "why" questions, with "optical recognition" questions and with real world scenarios which demand the proposal of an accepted network solution according to specific needs and restrictions. Student/users propose their answers by working in the "Network Editor", i.e. a special part of the program that allows them to edit the proposed network solution. The interface actions supported by Network Editor are supposed to exhibit "cognitive fidelity" [Collins 1996] to the real-life actions made by the expert. While in Apprenticeship students are asked to freely criss cross the cases [Jacobson et al. 1995] and create a list of case references by linking the problem situation to the cases on which they base their proposed network solution. Scaffolding to student answer-forming activities is offered by expert commentary emphasizing major points that students should bear in mind.

Multimedia in Teacher Education: A Small College Approach

Thomas A. Drazdowski
Education Department, King's College, Wilkes-Barre, PA, 18711, USA E-mail: tadrazdo@rs01.kings.edu

Abstract: Colleges of education in the U. S. have been challenged to model and integrate technology use throughout their curriculum in order to better prepare future teachers to use technology in their professional practice. This paper reports on how one college education program is restructuring itself in order to meet this challenge, and focuses on how the program converted its traditional "media design" course to become "multimedia design."

Introduction

Although many advances in educational technology have been made in the past decade and U. S. schools continue to invest millions of dollars in educational hardware and software, the vast majority of the nation's K-12 teachers have failed to adopt technology use into their daily classroom teaching. According to a recent study conducted by the Office of Technology Assessment [U.S. Congress, 1995], part of the blame for this failure to adopt technology can be attributed to colleges of education that prepare teachers, for as the study reported, "One conclusion to be drawn is that telling students about what is possible is not enough; they must see technology used by their instructors, observe uses of technological tools in classrooms, and practice teaching with technologies themselves if they are to use these tools effectively in their own teaching"(p. 185). Colleges of education have been challenged by such reports to model and integrate technology use throughout their programs and to design new courses which will better prepare inservice teachers to use advanced multimedia technologies in their future classrooms. This paper will focus primarily on how one college program has redesigned its traditional educational media course for preservice teachers to become a multimedia design course, and will also share information about the department's overall three year technology infusion plan. Problems and possibilities with such a restructuring effort will be discussed.

Infusion Plan

As all long journeys begin with a single step, the first step for our education program was a department meeting in the spring of 1994 which was held to brainstorm and formulate an action plan. From this meeting arose a three year technology infusion plan, which included goals for faculty training, a restructuring of all teaching methodology courses to integrate technology use, and a technology acquisition schedule for the department [Drazdowski, Holodick, & Scappaticci 1996]. Though all the original goals have yet to be achieved by the department, the plan continues to act as a strategic decision-making guide and as focus for subsequent discussions and actions. A new technology plan for 1997-2000 will be drafted this summer.

Multimedia Design Course

The multimedia design course for preservice teachers became a reality in the spring of 1996 with the opening of the department's new computer lab. The computer lab consists of the following components: 12 PowerMac student workstations each connected to a laser disc player with separate color video monitors; 1 laser and 1 color inkjet printer; 1 flatbed scanner; 1 digital camera; 1 video camera, vcr, and a monitor (to produce QuickTime Movies); a large DA-LITE Screen; and a teacher station with like equipment on a multimedia cart that also includes a Syquest 135 EZ Drive and is all connected to a Sharp ceiling-mounted LCD projection system. The main software packages utilized in the course are HyperStudio 3.0 (Roger Wagner Publishing) and PowerPoint 4.0 (Microsoft). The main student text is *HyperStudio 3.0 In One Hour* by Vicki F. Sharp [see

Drazdowski 1996 for a review of this text]. All computers are linked to the college network and Netscape Navigator is available for Internet browsing. The students in the course are senior education majors, both elementary and secondary, who are in their "Professional Semester" and are about to begin their student teaching experience. Students work in collaborative pairs, actively constructing knowledge as they research topics and solve problems. The professor's role becomes that of guide, facilitator, coach, and scaffold builder. By the conclusion of the course students have created and presented many effective multimedia stacks on a plethora of topics, ranging from mitosis and the solar system to beginning Spanish, from eating healthy and dental hygiene to black history, from evolution and English grammar to the battle of Gettysburg, the plays of Shakespeare, and a tour of Paris. Any of these multimedia products can subsequently be utilized by the student teachers in their field placement settings.

Challenges and Conclusions

Our efforts to make lasting change in our program have met with many of the traditional barriers to change that have been identified in the literature, such as adequate access to technology, proper training for faculty, administrative and technical support, budget restrictions, and as Fullan [Fullan 1996] identifies, overload and fragmentation. But the most daunting obstacle to change the program has found to date is the lack of technology-rich environments and technology-using cooperating teachers in our students' field placement settings. Finding school cultures that promote and encourage innovation can be a difficult task. To help solve the technology access problem, our department has purchased two laptop computers and color LCD panels that can be checked out for field use by our student teachers, and many have taken the opportunity to do so. But in the long term it will take the combined efforts of school districts and colleges of education as well as consistent and appropriate funding from local, state, and federal sources to initiate and maintain change. It is only through such partnerships [U.S. Department of Education 1996] that we will be able to foster a generation of technology using educators, and only then will technology be able to finally fulfill its promise to transform teaching and provide more engaging learning opportunities and curricular innovations [Carrol 1997] for students in U. S. classrooms.

ORGANISATIONAL FACTORS INFLUENCING ON-LINE REAL-TIME TELE-EVENTS

M Peta Dunkley, Surgical Skills Unit, Ninewells Hospital & Medical School, Dundee DD 9SY, Scotland,
m.p.dunkley@dundee.ac.uk

Norman M Smith, School of Informatics, University of Abertay Dundee, Dundee DD1 1HG,
n.smith@tay.ac.uk

Abstract: The attitudes of Scottish medical professionals to the introduction of a tele-education network as part of the training process for minimal access therapies were studied. A three phase investigation was carried out in order to identify the important strategic issues. This involved an initial questionnaire distributed to recognised tutors for minimal access techniques; in depth personal interviews with representative stakeholders involved in the organisational decision to join the video network and data collected using a Group Decision Support System at a workshop of clinicians unfamiliar with the system. The paper provides an account of the wide range of issues which the professionals identified as important during the selection and utilisation of video communications technologies for surgical training. A framework is proposed for analysing innovative IT or telecommunications projects.

This paper describes empirical research undertaken to determine the attitudes of Scottish medical professionals involved in the introduction of video conferencing technology in Minimal Access Therapy (MAT) training. It identifies the issues that medical professionals believe to be important with regard to their organisation's innovative use of IT. The respondents attitude and behaviour with regard to these issues will be discussed.

The National Health Service in the UK has undergone radical organisational change over the past decade, most especially with the creation of an internal market and of competition between previously collaborative providers of health care. At the same time, advances in medical science led to major changes in the way services were provided and this has had marked implications for the national provision of medical training (Cuschieri 1993).

This rapidly changing environment was the stimulus for the formation of MATTUS (Minimal Access Therapy Training Unit Scotland) and in particular the MATTUS video network for use in the training of postgraduate practitioners specialising in minimal access techniques. The establishment of a network of any significance required the participation of a number of geographically dispersed organisations with varying strategic priorities and differing degrees of openness to the use of developments in IT. While a number of telecommunications technologies are established, the uses of, and environment for, the proposed system meant that an innovative design required to be developed to suit the needs of medical users.

The investigation of the implementation was undertaken in three phases, consisting of a preliminary questionnaire, followed-up by semi-structured interviews and then a workshop. The questionnaire was distributed to all MAT (minimal Access therapies) clinical tutors in Scotland to elicit their attitudes to surgical training events, using real-time video and telecommunication systems. The study addressed system functionally, changes in established practice, and how these may best be disseminated. It also examined the effects of system implementation on the participants and process evaluation.

BEST COPY AVAILABLE

The second phase consisted of in-depth personal interviews with representative stakeholders in the decision-making process for the proposed MAT video conferencing system. The interviews were conducted by an independent team to facilitate freedom of opinion. The stakeholders were categorised into three broad groups; medical professionals, non-medical business managers and IT specialists. The interviews provided a unique opportunity to gather the opinions of individuals involved in this pilot video conferencing project.

The third phase consisted of a 1-day workshop attended, 'virtually', by medical professionals, mainly postgraduate practitioners, all having experienced the MATTUS live video network. The workshop participants were geographically distributed around the three main Scottish sites. The workshop was organised to allow issues that had been raised in the previous information gathering phases, to be explored in greater detail and improve upon the quality and richness of existing data. It provided the opportunity for a range of both, organisational and individual issues to be considered pertaining to the participants perceptions of the role, appropriateness and effectiveness of video conference technologies and its eventual acceptance as a distributed medical training environment.

To facilitate the capturing and structuring of the data generated by the workshop participants a Group Decision Support System (GDSS), based on the cognitive mapping technique, was used (Eden & Galer 1990). This particular group support technology was used to structure and analyse the qualitative data. It is recognised that organisations use GDSS's when problems are complex (Eden 1992), as in the case of defining organisational factors for successful tele-events.

The paper provides an account of the issues which medical professionals determine as important during the selection and utilisation of video communication technologies pertaining to the dissemination and interaction of surgical skills training.

An outcome of this 3-phase research programme is a proposal and action plan to support organisations seeking to implement and manage live video networked tele-events. Issues addressed include strategic implications, financial constraints, intangible as well as tangible benefits and coping strategies to satisfy leadership and user expectations.

Whilst real-time on-line video network technology is maturing rapidly for the dissemination of surgical training skills in interactive environments, it is proposed that a repertoire of techniques must be added to the presentation skills toolbox to ensure that utilisation of the available technology is maximised.

A framework is proposed for analysing innovative IT or telecommunications projects. This is designed to highlight the key elements which may cause difficulty and draw the attention of the implementation team to issues which will promote efficient and effective design and adoption of video-based systems in medical training.

Computer Conferencing to Support School-University Collaboration in Teacher Education—A Case Study

William J. Egnatoff, Faculty of Education, Queen's University at Kingston, Canada, egnatoff@educ.queensu.ca

Mark Danby, Faculty of Education, Queen's University at Kingston, Canada, danbym@educ.queensu.ca

Abstract: Teacher education is enriched when teacher candidates, associate teachers, and education faculty members discuss practicum experience and connect that discussion with work in education courses. A computer conferencing system was set up to support such interpretive discussion. Participants were given training, technical support, and suggestions on using the system in their professional practice. A study was designed to examine the form and substance of professional dialogue using telecommunications over a seven-month period that included two three-week practica. Participants acknowledged the potential of telecommunications, used e-mail as needed, but made very little use of the separate conferencing system. The paper examines these findings in terms of access, skills, and habits and interprets them in terms of technological change within the culture of teaching. The study is part of ongoing research and development to enhance collaboration between the university and schools in initiating teachers to their chosen profession.

1. Introduction

This paper reports on the voluntary use of telecommunications during the 1996-97 school year in a three-year project called Schools, Learning, and Telecommunications in Teacher Education (SLATE). In preparation for a new B.Ed. program having an extended practicum including school-based course work, the researchers wished to know how telecommunications might support collaboration between associate schools and the faculty.

Teacher candidates placed in SLATE schools for their practica were offered special opportunities: pre-practicum orientation visits to SLATE schools, working as a team during practica, collaborative teaching assessment, and workshops on computer applications including the use of a computer conferencing system.

The researchers explored how various telecommunications media—telephone, fax, e-mail, listserver lists, desktop video conferencing, and computer conferencing—fit the routines of teacher education, both to assist in organization, and in supporting professional dialogue. The researchers compared success in formally structured computer conference activities [Harasim 1995] with volunteer use.

2. The Telecommunications Study

Forty-six teacher candidates, 52 associate teachers, five principals (two secondary, three elementary), three vice principals, two faculty liaisons (the two researchers), and four research assistants collaborated in the study. Data were gathered through participant interviews, surveys, and field notes.

The researchers drew on experience in supporting teachers in the use of telecommunications [Egnatoff 1996] and on Danby's six years experience in administering a multi-faceted practicum program that had undergone recent major changes. The study was guided by a recent M.Ed. thesis [Christos 1996] on the SLATE Program that recommended more effective use of telecommunications to support professional development.

The telecommunications study examined patterns of use of e-mail and computer conferencing and explored the practicality of establishing a conferencing system for use by all teacher candidates in the B.Ed. program.

3. Preparing to Use E-mail And a Computer Conferencing System

The use of e-mail and of a listserver list for SLATE teacher candidates was readily established. Using e-mail had become part of the culture of university life and reliable infrastructure was in place. Establishing a separate conference system took the better part of a year: chosing suitable software (SoftArc's *FirstClass*), configuring a server on the Internet, and offering workshops, individual coaching, and support to participants.

No use was made of the system in the three elementary schools because Internet access was not readily accessible. The SLATE secondary schools could use the system because they had Internet access similar to what was available at the university, although with less bandwidth and hence slower response.

4. Findings: Voluntary Use of E-mail and Computer Conferencing

Two thirds of SLATE participants found e-mail valuable. Faculty-candidate exchanges dealt with announcements, practicum arrangements, SLATE surveys, and teaching. The number of messages per candidate ranged from 3 to 40. Faculty liaisons and school administrators also exchanged e-mail occasionally.

Use of the conferencing system was much less frequent and varied. Participants preferred other forms of communication. Candidates found it easy to talk amongst themselves and with their associates in the school. Most associates were not in the habit of regularly discussing their work as associates with one another. Most associates and candidates did not see any great need to share writing about their work with the faculty.

5. Summary and Discussion

This research report describes and analyzes a particular case of learning to use a new telecommunications medium while a faculty of education was undertaking significant program changes. The study was an opportunity to learn during the change, combining what had been learned in using telecommunications in the old program, in the 1996-97 pilot of the new program, and in the SLATE project. The study was an opportunity to document problems of access, the development of skills, and the establishment of habits of use of telecommunications at a time when access was being developed in schools.

In just a few years, use of e-mail at the university had moved rapidly along the path of growth, acceptance, standarization, and stagnation [Franklin 1990], shifting from a take-it-or-leave-it convenience to an institutional requirement. The same shift had begun in schools. Skills in using e-mail and a conferencing system were readily acquired, but habits of use for teacher education were governed very much by old habits of face-to-face communication and were strongly influenced by the lack of time to set reflections in writing. Given the option to take or leave the use of various media as teacher candidates saw fit, they took what fit well with their view of their work during the practicum, a component of the program quite distinct from university-based course work.

Bowers [Bowers 1988] construes what goes on in schools as an "ecology of relationships . . . regulated largely by the patterns (information codes handed down from the past) the participants have internalized as part of their taken-for-granted view of the world." The structure of the old program, with its short practica in which candidates found themselves fully pre-occupied keeping up with day-to-day preparation and classroom practice and with its separate blocks of university course work in which candidates were in different groups than their practicum groups, mitigated against the establishment of computer-based conferencing for collaborative reflection. Ongoing research will assess whether computer conferencing suits the habits of professional dialogue that emerge in the new B.Ed. program.

TEECH: Forging an Electronic Community for Leaders of Teacher Enhancement Projects

Joni Falk, Brian Drayton, Gloria Jacobs, Jack Lochhead
TERC 2067 Massachusetts Avenue, Cambridge, MA 02140
E-Mail: joni_falk@terc.edu

Abstract: TEECH (Teacher Enhancement Electronic Communications Hall *http://teech.terc.edu/*) is a three year project, funded by the National Science Foundation. It aims to advance the work of Teacher Enhancement projects by fostering increased collaboration among leaders in teacher development through the formation of an electronic community utilizing the Interment. TEECH draws on the strengths of over one thousand principal investigators and senior staff of teacher enhancement grants from the National Science Foundation, the US., State, and local Departments of Education. Its purpose is to encourage communication, collaboration, joint exploration, and pooling of this community's collective resources. This paper reports on challenges, strategies, and evaluation of this electronic community.

The users

TEECH, a project funded by NSF, aims to increase collaboration between leaders in the field of the field of teacher enhancement. These "leaders in the field" are primarily people who had written grants and received funding from the State or Federal government to improve aspects of teacher professional development. An initial needs survey (Falk, 1996) was sent out to 465 Principal Investigators and we received 255 responses, a 57% response rate . Their responses to our survey revealed that Principal Investigators (PIs) of teacher enhancement grants could not be considered as one cohesive community. The backgrounds of these PIs spanned a broad spectrum of expertise that included fields. The only factor that all PIs had in common was that they had obtained funding in order to conduct a teacher enhancement grant to improve math and science education k-12. Our initial needs survey showed that 91% of our users had access to the Interment. 84% replied that they had used e-mail, 56% had used gopher, 46% had used mailing lists, and 41% had used the World Wide Web.

While these Principal Investigators did not share a common background, a common professional vocabulary, or a common theory of teacher change, we hoped that they would use the diversity of their backgrounds to enrich each other. We were encouraged that they identified themselves as being most interested in discussing shared topics of concern such as Teacher Change, Professional Development, Assessment and Educational reform. In fact they rated these topics higher than their specific interest in either math or science or a specific grade level range to which their project was aimed.

The challenge

Unlike many virtual communities where users sign up because they have a desire to connect with others who share a special interest such as genealogy, or a love of Jane Austin novels, these principal investigators did not self create their community. The community was formed, in large part, because founders saw the need to improve collaboration, participation, dissemination between teacher enhancement projects so that projects could learn and profit from each other. This idea has clear merit. The challenge was to convince leaders in the field that such a community would help expedite their work rather than become yet another diversion and consumer of their time. Each of these investigators belong to smaller communities, which consist of staff who work on their project and other colleagues within an outside of their institution. How would this community add to the interactions that they were already having on subjects of Professional Development? Our challenge was exacerbated by the fact that many of these people were competing against each other for future rounds of educational funding. While they had a desire to share with each other there was often competitive edge. In addition, at the beginning of this project, while 96% of our population said that they had Interment access less than half (46%) reported having ever connected to the Web.

Strategies

During its first two years TEECH has developed multiple strategies to meet the needs of this community. These have included listservs moderated by leaders in the field, electronic seminars, on-line lectures given by leaders in the field made available on our Web site through Real Audio and text copies, and a database of PIs and their teacher enhancement projects. We also have made attempts to combine these formats, having a real audio discussion with a listserv connected to it.

Evaluating Participation

In *The Virtual Community*, Rheingold describes his first experience of being a part of a virtual community. He writes "I soon discovered that I was audience, performer and scriptwriter, along with my companions, in an ongoing improvisation." What we discovered on TEECH by looking at the interactions of our users was that not all members shared Rheingold's versatility for assuming each of those different roles. While some were performers who felt comfortable expressing their views others preferred to be the audience. Some investigators preferred to read papers than listserv dialogue which has an element of improvisation. Most preferred to read papers published on our site than to submit papers for publication. In the initial needs survey it was clear that of those who used the Web 53% used it to browse or retrieve information while only 35% used it to post to listservs or to publish.

Our multiple modes of interaction developed to serve different user types. Papers by leaders in the field and resources on critical subjects provide important core material for the users. Those who prefer the role of "audience" rather than performer can retrieve information without feeling that they have to post or publish. Those who want to contribute can do so. Lectures, similarly bring key speeches to investigators. These lectures provide audio, transcripts and overheads. Those who feel more comfortable experimenting with technology use the audio. Those who are more comfortable with text only view it in that mode. A searchable database allows Principal investigators to find other leaders with similar interests and also similar projects. They then can contact these projects by e-mail without being part of a large discussion. TEECH also has had several active discussion groups. Those who post are more comfortable in the "performer" role. they are also comfortable with the aspect of improvisation in that the conversation is organic and takes sometimes unexpected turns. In contrast, there are those who do not feel that they can join a moving dialogue. One user wrote:

> Why have I not actively participated thus far? I would say that lack of time has been the main reason. I have saved various messages, including your message of 2 weeks ago, with the intent to respond, but framing a brief thoughtful, response takes some time- and as time passes it seems that the heat of the opportunity has passed. Perhaps with time I will feel that I can just dash off a quick response or thought, but given the spunky nature of some of the discussion, I'd rather make sure that my words are appropriately chosen.

Yet, interestingly, we found that those "in the audience", silent participants of discussions who received the mail but never posted, also received a great deal of benefit. Following one very active listserv we sent a survey to both those who had posted and those who had not. Responses showed that both groups thought that the discussion was useful (95% of contributors, 82% of non contributors) and relevant to their project's work (86% of contributors, 82% of non contributors). While 67% of those who had posted shared the conversation with their colleagues, a similar 65% of silent participants had done so as well. The only area in which we saw a significant difference between contributors and silent participants was whether they corresponded or collaborated with a PI who had posted to the list. On this question 43% of active participants reported having had such a follow-up communication where as none of the silent participants reported doing so. (P=.002 by Fisher's Exact Test)

Lessons Learned

The TEECH community is very diverse. These Principal investigators are diverse not only in their professional fields, but in their comfort with the Interment and also in their interpersonal style of using it as a mode for communication. It is important to provide multiple avenues of interaction, for the performer to express and share the work that is being done, for the scriptwriter to be able to carefully craft papers for his peers, and for the audience who profits by the knowledge gained and by sharing with colleagues off line.

Hypermedia and Learning Goals

Laura Farinetti
Dip. di Automatica e Informatica
Politecnico di Torino, Torino, Italy
E-Mail: farinetti@polito.it

Anna Rosa Scarafiotti
Dip. di Matematica
Politecnico di Torino, Torino, Italy

Abstract: In this paper we define our interest in hypermedia tools for learning, considering in particular the aspect of "learning by doing" and problem solving. Our interest is directed specifically in the field of mathematical education, and this is proved by our effort in designing and implementing hypermedia tools for teaching how to solve problems in different mathematical topics.

1 Hypermedia as Learning Strategy

Through hypermedia systems we believe to overcome, at least partially, the problems and the obstacles related to learning [Farinetti & Scarafiotti, 1995].

In a teaching and learning process we try to expand the knowledge base of the students, but we also try to communicate the knowledge of procedures and methods for studying and thinking, so as to involve the learner in an active and growing way. This task requires a good ability in encouraging the students' curiosity and interest, and in gaining their attention.

A teaching module supported by a hypermedia tool can encourage even the most reluctant teacher in "getting out of the desk", since the role of knowledge transmission is committed to the tool, in which the teacher sets his o her fantasy and creativity free; the hypermedia tool can become a "virtual friend" to study with, thinking over the subject in a personal way.

Specifically we agree with Marquesuzaa et al. [1996], who identify the goals of a hypermedia system that want to be an help for learning through the interaction between actors and methods: take better advantage of the facilities that multimedia technology provides, and help the users become more responsible for their progress.

What we said previously is particularly valid in the case of mathematics. The learning theories related to this discipline make the distinction between declarative knowledge (when we know the "facts") and procedural knowledge (when we are able to apply methods and strategies to solve problems); the more careful is the study of mathematics, the more evident is that learning is built through the creation of connections among concepts and processes.

Most researchers therefore believe that it is really important to guide learners in identifying not only the concepts but also the paths among them, looking for all the reasonable ones. The teachers then should help the students in decomposing a chapter A of mathematics, and in building it again according to a personal logic, obtaining a chapter A'; a distance exists between A and A', but A' is understandable and usable by the student; we can observe that the building of A in A' happens only if the user has in mind a context map of A.

In the text-books about mathematical learning, ample room is given to problem solving as a test for evaluating the learning process, and according to the philosophy of "learning by doing" [Farinetti & Scarafiotti, 1996]. We therefore have great expectations about hypermedia tools that help the process of solving didactic problems. In addiction to this, open hypermedia tool will give the teachers the opportunity of making their problem collection grow, offering a didactically valid framework for building questions.

A good hypermedia system will therefore be designed according to cognitive apprenticeship requirements, and will give particular attention to six fundamental aspects in the learning process:

a) modeling and explaining: understanding the model of what we have to learn is the first step in learning; a hypermedia tool which shows and explains the reasons why something happens is likely to grab the attention of the students and to motivate them more than many words;

b) coaching: hints and feedback can guide the students in performing their tasks; a computer teacher is infinitely more patient than a real one.

c) scaffolding: the support level of the teacher changes according to the increase of the students' skill, and gradually disappears; a hypermedia tool can provide different educational paths for different skill levels, or can be programmed to change its behavior dynamically;

d) articulation: a consolidation of learning happens when the students are encouraged to think of what they are studying from different perspectives; a hypermedia tool can offer the integration of many different points of view and link them together, leaving to the student the task of understanding the real meanings of the links;

e) reflection on performance: evaluation or self-evaluation is fundamental for correcting errors and misconceptions in the building of knowledge; hypermedia tools can offer different ways for performing this task;

f) exploration: the comparison between different methods and procedures for problem solving helps the students acquire their personal strategies and stimulates their creativity; hypermedia tools can list different methods, relate them in the case of one exercise or among many exercises through the use of analogies and similarities.

2 The Design of a Tool for Learning Numerical Analysis

The tool is essentially a collection of exercises with helps, hints and solutions. We defined three different categories of exercises:

a) quizzes
b) step by step exercises
c) complex exercises

The exercises of categories a) and b) are grouped according to the topics of numerical analysis; category c) contains exercises that consider the whole content of the course. The level of difficulty in each category increases from one problem to the following one.

The student studies a topic, solve the problems of category a) related to it, deals with the related exercises of category b), and moves to the following argument; after having considered all the topics, he can check his level of knowledge solving again all the exercises of category a) and using the feedback to revise the contents. Finally he can solve the exercises of category c) for testing his skill in using general strategies and procedures.

New Media Enhanced Education: more than to add new resources

Joan Ferres, Pompeu Fabra University
Antonio Bartolome, University of Barcelona

Teachers and educators are worried about how to take advantage of newmedia and/or new technologies. But they focus the problem from theperspective of the introduction of new resources that would help to reachold objectives, and, some times, with old methodologies. The mediaare used in the service of memorizing, of structured learning, ofreproductive teaching as denounced by Freire, of knowledge as a contentthat you can to move from one recipient to other as Popper criticized.

When we use the new media in our educational systems, we must beconscious of the changes that these media have produced in our society,because we are wrong if we think that we will be able of filling the oldbarrels with this new wine without problems. This paper shows asynthesis of our work during the last years, synthesis that we presentaround two key ideas: Education in a show-culture, Education in aparticipation-culture.

We know that some of the ideas of this paper will sound strange, andthey can to generate a strong controversy, specially between not technologynear teachers and professors. In so few pages it is difficult to developthese ideas in depth. And we both are not-English speakers. However,read carefully the next lines and reflect on them.

A. Education in a show-culture

For the first time in the history of Humanity it is possible toassert that we live in a culture of the show. And this is not only becausethe Audiovisual Communication technologies put every kind of spectacles atcitizen's disposal 24 over 24 hours, but also because thosetransform in spectacle every reality when touched: from electoral shows toelectronic churches. How does it affects to education? How to educate in ashow-culture?

The first to do for a lucid educator is to become aware of personalchanges imposed by cultural changes. Diverse cultures, when they imposechanges in communication instruments and expression forms, they finish upby imposing changes in perceptive habits, mental processes,attitudes, preferences. In other words, cultural changes derive inperceptive, attitudinal and mental changes. Every communication worker thataspires to be effective in a cultural change age has to adapt tomodifications that the new culture imposes in the receivers. Whichones are the changes derived from a show-culture? We can to distinguishbetween modifications at perceptive level, at mental level and at attitudeslevel.

1. From a perceptive point of view, the iconosphere culture move tofavour the feelings over the thoughts. In a show-culture it is moreimportant to contemplate than to think. It outweighs the concrete over theabstraction. It favours the sensibility over the reflections,dynamic over abstract dimensions. The show-culture is the culture of senseshyperstimulation, visual as well as sonorous one. It is the culture of thefear to the silence, of the rejection of the static state. It is theculture of "zapping", of the continuous perceptive change, of thesenses reward, of the accelerated rhythm, of the vertigo.

2. From a cognitive point of view, the show-culture move to favourwhat is emotive over what is rational, simultaneous over linear, intuitiveover thoughtful. The iconosphere culture contributes to power the kingdomof the emotion over that of the reason. It does not mind so much ifit agrees with the represented reality, from an ideologic point of view aswell as from an ethic one, as if it likes, it satisfies, usually at mostelemental level. It is the culture of the hypertrophy of emotions asconsequence of the senses saturation, but also it is the culture ofcontinuous use of the psychological mechanisms of identification withrepresented characters and of the projection of diverse feelings tospectators.

From the mental point of view, the show-culture represents at thesame time a different manner of understanding the world, not in a linearway but in a simultaneous one, not in an analytical way but in a syntheticone, no in a rational way, but in an intuitive one. From thesystematized and hierarchical humanist culture it is passed to mosaicculture, characterized by the dispersion and the random chaos. It is aradical different form of constructing, not so much from cause-effectrelation processes as from the simple association, from the relationby contiguity or similarity.

3.These modifications have their repercussions in the sphere ofattitudes. For instance, the "zapping" -use of remote control to jumpcontinuously from one channel to other- stops being only a behaviour infront of TV set, to convert in a vital attitude. At every level ofour lives, it is moved from the possibility of change to the necessity ofchange. The space and the time are not lived in a linear way but in asimultaneous one. From "a time for each thing" to "every thing at the sametime". The emotional reactions are moved to favour over rational.The show-culture is, definitively the culture of zapping, of hypertrophy offeelings, of kingdom of senses, of intuitive thought.

The educator could to react in front of this analysis arguing theneed of compensatory measures. He/she could to allege that what educationalinstitutions have to do is filling the empty spaces that this show-culturehas created. He/she also could to defend that Education must besituated in the opposite of described parameter, to face up to theexaggerations of this show-culture. This is not valid option because itwill not be educationally effective. Of course, it is essential thateducator compensates the generated voids, but this has not to bedone -it cannot to be done- from communication parameters opposed to thisculture. If education is, primarily a communication process, it will beeffective only if it is capable of connecting, of syntonizing with the receptor of its own discourse. And to syntonize with receptors moldedby this show-culture it is necessary to start from the same parameterimposed by this culture. If the new media have deeply modified the culturewhere they have born, and if this has deeply modified the way we seeand think, it is essential that education knows to modify deeply also itsown schemes and criteria to adapt to these modified subjects. To modifyitself not to renounce its objectives but to remain faithful in theessential to them.

To educate in a show-culture has to implicate to assume a certainprimacy of the concrete, of the senses, of the feelings. To make agile therhythm of teaching/learning process. To incorporate visual, intuitive,global, dynamic methodologies and strategies. To educate in thisculture implies to assume these values but not to remain in these, notconsidering them as an absolute reference, but using as springboard, aslever, as power, as catapult, as motor to improve procedures that take tocritical analysis, to abstraction, to reflection.

B. Education in a participation-culture

To define our culture as a participation-culture requires amultidisciplinary analysis: from the sociology, from the politicalanalysis, from the social psychology... Here we are going to explore howthe dominant technology is evolving toward an interactivetechnology, and its applications change more and more toward participativeones.

In any case, ours is not the first culture with high participationlevels. And it is not the first one where this participation is stopped inits way toward the actual taking of decisions. Knowing and appropriatingthe participation mechanisms is a step forward to a democraticpower. Day after day we are being convinced that today the democraticparticipation is based not only or not primarily in the voting, electoralcampaigns or in the demonstrations, meetings,... but in the access tocommunication media.

During the last decades it has been assumed that Information ispower, that the control of Media is power. Perhaps, the starting point wasthe propaganda policy of Nazi government, in Germany at 30's. So, theparliamentary actuations or street demonstrations are, more thanpower instruments, means to get the access to great Media, authentic powersupplier. But this is changing.

What is changing is the old discourse that conceives the informationas a power source controlled by a few ones, as described by Ramonet (1980)or, in a more entertained and right way, by Jerry Mander (1977) whenremembered that McLuhan used to speak of a global village with adrum, but that McLuhan had forgotten that there was only one drum, and onlya few people played it.

How is it producing this change, that I consider still in itsbeginnings? I think that there are several factors derived from theevolution of technology, that are determining the change. Other factors arerelated with a society based in the consumption, and that it dependsof consumers to run on.

As consequence of the technological development and of the rules ofthis liberal and consumption based society, the television is characterizedby:
. multiplicity of programmes: specialized channels
. multiplicity of dealers
. multiplicity of channels: cable, satellite, Internet....

If we begin from the lowest level of this reality, we find the"zapping" or continuous use of remote control jumping from one channel toother. We can to analyze deeply this use: before the spectator sat in acomfortable sofa opposite the tv-set to "watch what there is". Now,the situation is similar but with the remote control in one hand, takingdecisions about what to watch. Of course, the spectator has been lesspassive than it seems. But the difference that now he is taking thesedecisions. And these ones involve the need of defending the owndecisions in front the other sofa's companions. Well, I am speaking of mychildren, 4 and 8 years, discussing and selecting the preferredprograms.

Higher in the scale, we can find new participation forms, arriving to"tv-broadcasted games" but always in this centralized or in-a-star-waydistribution of information. And we find the "tv a la carte": now thespectator does not choose between a limited number of actuallybroadcasting channels but he/she selects one program that begins to bereproduced specifically for him/her at this moment. And we can arrive to TVby Internet as the Vivo Software Inc. proposal (http://www.vivo.com).

The next step is to move from receptor to transmitter. The formertechnology let the community channels by cable, the local broadcastcenters, alternative transmitter, video distribution, counterinformation...but today with Internet the audience can to be as wide as theplanet.

This takes us to a change in the conception of communication: fromaudiovisual to multimedia (Hodges & Sasnett, 1993), from one-way to two-way(Gayeski & Williams, 1985), from information distribution oriented systemsto participation oriented systems. If, as Victor Hugo said, there isnot anything so powerful as an idea that finds its time, today the GlobalVillage of McLuhan (1964) is finding its time thanks to Internet, but it isa new village where it does not mind so much the drum as this assemblywith a participation so far and so near to some descriptions ofMargaret Mead, but, this time, "cyborg citizens in electronic agoras"(Mitchell, 1995).

To educate in a participation-culture supposes to educate in the useof the technology to communicate with all the world, to let our own voicebe heard, to stablish networks over the borders, to generate the owninformation, to access to relevant information where it is. Theelections at school, the social education... are important resources butthe socializing process today has to be based in the technology. A socialeducator without access to technology is, today, an educator that has losthis/her arm, the right. An Education that does not prepare for thistechnology of participation, is seeding obstacles in the democracy path.

Abstract

At Wright State University, education students construct a professional portfolio that documents the pre-service teacher's growth. The portfolios are modified throughout their program and may be used with potential employers. Now the students create web pages that serve the same basic purpose and access to hypermedia. The webpage may provide hyperlinks to instructional resources in the student's area of concentration, and has the added benefit of video clips that illustrate the pre-service teacher in action. The use of this electronic may also serve to demonstrate the candidate's mastery of educational technology.

Educational technology, as defined by Awbrey (1996) is "a dynamic system -- employing a combination of human and non-human resources to create effective learning environments." It is imperative that hypermedia, multi-media and telecommunications become as commonplace as chalkboards and textbooks in that learning environment. Recognizing the importance of educational technology, the National Council for Accreditation of Teacher Education (NCATE) requires preservice programs at colleges and universities to include educational technology in all coursework in which early childhood, elementary and secondary level teachers are prepared (Richardson, 1994).

The Teacher Education Department at Wright State University (WSU) in Dayton, Ohio is taking that requirement very seriously. Pre-service teachers conduct on-line searches to locate publications from a variety of sources; use electronic retrieval systems, such as ERIC and search engines, like Yahoo and Alta Vista, to locate and download research from on-line journals. In presenting their term papers, students model "best practices" by designing and presenting multimedia presentations using applications such as *Hyperstudio, Power Point, Astound, Digital Chisel* and others. In addition to accessing the internet for on-line chatting and conferring with their professors, Wright State's education students discuss topics and debate questions posed by professors and others in their classes via listserves and user groups. As a study in comparative education, students may choose to interact with education students in other parts of the United States and Europe.

At Wright State University, education students construct a professional portfolio that documents "Teacher as problem-solver", the model on which WSU's teacher education program is based. These portfolios include an auto-biography, a resume, a discussion of educational philosophy; a self-evaluation of personal strengths, and measures of teaching and learning styles. Students reflect on specific skills in which improvement may be needed. Records of field experiences, pictures of classes with whom the pre-service teacher has worked are also retained. Documentation of expertise in major academic areas as well as congratulatory announcements and letters of recommendation is also housed there.

In addition to the "hard copy," other electronic formats of the professional portfolio have been considered. Pages of a the portfolio were scanned and pressed into a compact disk format. Although very portable, the CD format does not lend itself to frequent updates. In addition, paper copies, such as transcripts and letters, are not as readable in a CD format as they are in the original and the scanning of photos and graphics makes high memory demands. Pre-packaged portfolio programs, such as the Grady Profile and Scholastic's Electronic Portfolio are available to collect samples of student work and may include photos, pictures and other art work that has been scanned.

Another format for the portfolio that offers easy updating, almost unlimited memory, flexibility, easy accessibility and opportunity to utilize other forms of educational technology is the web page portfolio. In one section of teacher education classes, each of the 21 pre-service teachers was constructed an 8-10 page personal, professional web page that is located on the Wright State's College of Education server (www.ed.wright.edu). A couple of students chose to write their web page in html, some utilized Adobe's *Pagemill* or other applications from on-line services, such as Busy Teachers web page for web site construction. These student web pages include much of the same information as the traditional hard copy portfolio, with the addition of Quicktime movies -- short video clips showing the pre-service teacher in action. Students designed their pages according to personal preferences and often reflected their area of concentration (social studies, language arts, etc.), level of certification (elementary, secondary, etc.) and outside interests (hiking, biking, etc.) in their theme, backgrounds, and/or images. Students' web pages also included an area in which they posted the addresses of "favorite web sites." These URLs provided quick access to locations of personal interest, as well as home pages of educational organization (ASCD, NEA, AFT, etc.), and resources for teaching in the students' areas of concentration.

As the students' level of comfort with and expertise in using educational technology develops, their portfolios will be modified and reflect this growth. Students will continue to update their traditional hard copy portfolio as they update their web pages. When students are seeking their first teaching positions, they will be able to present their hard copy portfolios to their potential employer as evidence of their skills or, if the employer has access to the Internet, be able to log into the Wright State University Homepage and demonstrate their skills.

LEARNING PROOF TECHNIQUES THROUGH VISUALIZATION

Jane M. Fritz
Faculty of Computer Science
University of New Brunswick
Fredericton, New Brunswick, E3B 5A3 Canada
jane@unb.ca

Abstract: The art of constructing a mathematical proof remains a challenge to large numbers of students. Constructing a proof is a challenge to teach. It is also a challenge to learn, understand, and appreciate. This paper describes a proof tutor, a web-based application that provides students with reinforcement in the several components of proof construction, given a mathematical statement to prove. The application supports the learner in choosing an appropriate method of proof, then guides each step in the proof, using user-selection of step rationale as well as visualization of the mathematical process involved in moving from the current step to the next. Performance support is provided in the form of a linked mathematics dictionary.

The Motivation

The teaching and learning of what constitutes a sound mathematical proof is an acknowledged problem in mathematics education [Solow 1990]. The abstract nature of proof seems to be such a mystery to the majority of students that it often is disguised as something less intimidating, or even passed over in a general curriculum. The application discussed in this paper was designed for students taking a course in discrete mathematics, where a large part of the course content is the mastery of proof. The objective of this application is to strengthen the user's understanding of the process of mathematical thought while reinforcing a systematic approach to the construction of proof. Because the students' background in algebraic manipulation is often weak, performance support is provided through the inclusion of links to an on-line mathematics dictionary.

The Learning Environment

This application is used in two ways: by an instructor in the classroom to enhance the lecture experience, and by on-line use of a learner to reinforce the material. It can also be used for self-learning in lieu of classroom experience, although we have not had experience with this approach.

Guidance Through the Process of Proof

The application can be approached from two directions. Either the user may be given a random mathematical statement to prove, with the user choosing the method of proof, or the user may ask to practice a particular method of proof, in which case appropriate example statements will be displayed. For some methods of proof, such as mathematical induction, part of the process of establishing method is to lead the user into articulating both the starting point and the desired final statement, so that the success of each intermediate step may be evaluated. For other methods, such as direct proof, the "opening statement" is not always clear, and so the user is directed towards forming an opening position that is likely to lead to success [Levine 1994]. Once the user has a statement to prove, and an approved method to follow, the step by step process is guided. At each step the user is given a choice of mathematical definitions or laws that might or might not be suitable means by which to move along a path towards reaching the desired conclusion.

Several of the laws (or rules) used to advance a proof are animated for the user once a choice has been made, such as application of association, commutation, distribution, modus tollens, modus ponens, and transitivity. The development of the animation of the application of laws of mathematics and logic to expressions or statements is an on-going process.

Use of Performance Support

An associated computer-based application, MathDef [Fritz 1996], is integrated into our proof tutor insofar as any term that is not familiar to the user, or for which the user needs refreshing, can be linked to the definition available within MathDef. Additionally, MathDef is a multi-level dictionary, so that an expanded explanation of term is available for several topics.

Portability of Technique

This project is in the process of being ported from ToolBook to the Web to expand its portability. It also is portable with regard to use. It can be used for current course work and for remedial study; it can be used to enhance teaching by an instructor and to provide self-study for a student. It is felt that the presentation methods used in the proof tutor can be used with effective results in other areas of mathematics teaching.

Future Work

This is an on-going project that continues to build functionality in terms of: the animation of the application of mathematical laws to expressions; the number of proof methods that are accommodated; and, the degree of interaction with the user. As well, the supporting application, MathDef, continues to be expanded in both the collection of definitions of terms and in the number of those terms for which further levels of explanation are available.

Abstract

Schools are being faced with a myriad of internal and external forces that demand change. In an attempt to reconcile crowded classrooms, lack of resources and diverse family values, many families are seeking educational alternatives. The Nechako Electronic Busing Program™ is an electronically mediated K-10 distance education program that supports parents in the education of their children in non-traditional settings.

A recent addition to the field of distance education in British Columbia is an innovative program called the Nechako Electronic Busing ProgramTM. Located in the geographic centre of British Columbia, School District 91 (Nechako Lakes) enrolls approximately 5500 students in 20 public schools. These students are distributed throughout 8 communities that are separated by 40 to 100 kilometers of sparsely populated agricultural land. Yet one small elementary school of 90 students also enrolls an additional 440 students from all across the province of British Columbia. These are the students of the Nechako Electronic Busing ProgramTM.

Many parents, for a wide variety of reasons, have chosen non traditional methods of schooling for their children. The most common alternative is to school the children at home under the direction and guidance of the parents. Whether these decisions are made for philosophical or pragmatic reasons, few, if any, support services are offered by the public school system. In the early months of 1993, a small group of parents approached School District 91 (Nechako Lakes) with a request for assistance. These parents wanted to continue to be responsible for the education of their children, but they also wanted to be able to discuss educational issues and to be supported by a certified teacher.

In order to respond to this request, the District took the opportunity to pilot a unique concept it had been exploring; an electronically mediated distance education program. Each of the thirteen families were provided with an Apple IIe computer, a modem and an e-mail account in order to communicate with an assigned teacher on-line. Families consulted with the teacher and each other on issues ranging from pedagogical concerns such as curriculum, assessment and evaluation, to more pedestrian communiqués that dealt with the arrangement of group picnics and skating events. This proved to be such a constructive and successful pilot project, that it was expanded to enroll 225 students from 13 other school districts in the fall of 1994.

The model used by the Electronic Busing ProgramTM is built on a high degree of trust. Parents want what is best for their children and want the educational program they use to accommodate the child's unique needs rather than the educational system's needs. The Electronic Busing ProgramTM has tried to make this flexibility possible. Teachers on-line articulate the Ministry of Education's curricular learning outcomes to parents, provide assistance in planning and preparing a student learning plan, suggest appropriate resources to support such a plan, and offer assistance to the parent in selecting samples of student work that can be used to demonstrate that the outcomes are indeed being met.

Teachers on-line do not lay out a course of studies that all students must complete. Instead , they work directly with parents in helping them meet the child's individual needs. This type of approach works well with parents who desire a high level of involvement in their child's education and have a high level of commitment. It may not work well for all families but what it does provide is an unprecedented level of flexibility and control being placed in the hands of the parents who are treated as true partners in the process. There are many ways to achieve the learning outcomes described in the Integrated Resource Packages, and thus the choice of when, and how particular learning outcomes will be addressed is left in the hands of the parents.

Students are not assigned to teachers on the basis of traditional age/grade/subject groupings but as family groups located in specific geographic areas. This may stretch the skills of the on-line teaching staff, but it has so far facilitated better and more efficient communication between parents and teachers online, allowed for the natural integration of curriculum across grade and subject boundaries, and simplified the process of reporting. Recent discussions have centered around the notion of creating broad groupings of students (primary, intermediate, junior secondary) but while this move might capitalize on certain teaching skills and experiences, it might create problems for parents in terms of working with several teachers in an online setting. Parents may be offered the choice of working within the framework of a family grouping or working with several different teachers according to the approximate grade levels of their children.

A ministerial review of the program occurred in the spring of 1995, and the major recommendations indicated that in order to receive future funding, the families of the Nechako Electronic Busing ProgramTM would have to adhere to the British Columbia curricular learning outcomes and the progress of the students would have to be accounted for. Prior to this time, families were encouraged to follow B.C. curriculum and they were encouraged to participate in the credentialling process. This, however, had not been a requirement. The results of the review process were clear, however; failure to move the program to have all participating parents adhere to B.C. curricular outcomes and to have teachers account for student progress would result in the removal of provincial funding. For some families, these changes presented philosophical conflicts that caused them to leave the program, but the vast majority returned for the 1995-96 school year.

Steps were taken in the 1995-96 school year to establish policies and procedures to facilitate the Ministry's adherence and accountability directives. A great deal of discussion within the program focused on the pending changes and how families could supply sufficient evidence for teachers to make a professional judgment of students' progress. For students in the elementary grades (K-7), parents would minimally submit a learning plan outlining the learning outcomes students would be working on. At the end of the term they would indicate which outcomes had been completed, and they would provide sufficient evidences of student learning in order for the teacher on-line to determine that satisfactory progress was being made.

Students in the junior secondary grades must follow a more rigorous model and submit sufficient evidence for outcomes they have completed in each of the curricular areas. The educational programs of students in Grades 8 to 10 are more structured than those of the earlier grades, and this is due to the content-driven nature of the courses. Upon the submission of sufficient evidence for each learning outcome and curricular area, students are assigned a satisfactory grade. For grades beyond a C, criteria are developed and communicated at the beginning of each term.

Another review of the program was conducted in June 1996 to ascertain how the program planned to deal with the Ministry directives of adherence and accountability. It was determined that there were clear policies and procedures in place to ensure adherence and accountability and that the Ministry's expectations were achieved. As of October 21, 1996, the Nechako Electronic Busing ProgramTM became recognized and funded as an electronic distance education program for the province of British Columbia, enrolling approximately 440 students from all across the province.

At present, each family enters into a payment free lease agreement with the District for a multimedia Pentium PC that is equipped with a 28.8 fax/data modem. Further, each family is provided with:
· access to the Internet, e-mail and toll free voice access to an teacher-on-line
· ongoing training and support in the use of technology for educational purposes
· a bundle of educational courseware produced by the Computer Curriculum Corporation
· access to the E-Bus TM WebSite which contains British Columbia curriculum learning outcomes, support for instruction and support for evaluation
· a resource allocation of approximately $200 per full-time equivalent student to purchase materials to support the child's learning program.

Parents continue to assume the role of the primary instructor of their children. They are adhering to British Columbia provincial learning outcomes and are responsible to choose whatever resources and pedagogy that they determine are best for their child's learning situation. Further, samples of student work are shared with a teacher-on-line so that report cards may be written. In the intermediate and secondary grades, criteria are offered for students who wish to achieve marks above a satisfactory level.

The Nechako Electronic Busing ProgramTM does not fulfill the needs of all students or families. It provides a very real alternative to conventional models of public education for parents who want a direct involvement in their children's education, an alternative to overcrowded schools, an escape from unsafe learning environments and allows for the provision of additional curricular pursuits the students or parents choose.

The future of the Nechako Electronic Busing ProgramTM is exciting and promising. Partnerships are being developed with other educational jurisdictions to allow for the provision of services that draw on the experiences gleaned to date. We are also exploring ways to incorporate this program model into other educational settings such as storefront schools and non traditional classrooms. Steps are currently being taken to streamline the evaluation and reporting of student growth and to develop programs for the senior high school sector. Other national and international markets are being explored.

The Nechako Electronic Busing ProgramTM provides a model of elementary and middle school education that draws on the strengths of committed parents, the tools of electronically mediated communication and the experiences of a group of professional distance educators.

Assignment Responses as a Function of On-line versus Classroom Presentations of a Course on Dreams

Jayne Gackenbach, Ph.D.
Computer Outreach, Grant MacEwan Community College, Canada
jgackenb@gpu.srv.ualberta.ca

Abstract: Three groups of students were separately taught introductory material on dreams in either a traditional classroom setting, a mixed classroom and on-line setting, or in a completely on-line setting. After this material was presented their attitudes towards dreams were assessed. After confounding variables were controlled, only one of the nine dependent variables showed a sample effect. Therefore mode of presentation in general does not affect the attitudinal responses to the material at least when it comes to an introduction to dreams.

In the fall of 1995 I was asked to develop an on-line, non-credit course for a local community college in my area of expertise, dreams. "Unlocking the Secret of Your Dreams" consists of five lessons which teaches the student to interpret and work with their own dreams, both alone and in an electronic group sessions. Each lesson is accompanied by an assignment where students put what they have learned into practice, and answer a questionnaire about their experiences. A more detail on the registration page for the course (http://www.outreach.org/dreams).

Parts of this course have been or are currently being administered in a variety of settings including traditional classroom teaching, a combination of traditional classroom teaching and on-line presentation and only on-line presentation. The purpose of the present paper is to compare some of the responses of the students to the same questions about the course activities as a function of the setting in which the materials are delivered.

Method

In the fall of 1995 part of the first assignment was given to students in an Introductory Psychology class I was teaching following an introductory lecture on dreams. The lecture material was essentially the same as that presented in the first lesson of the on-line course. This data is compared to the first assignment responses of the beta subjects, who agreed to test the course at no charge in the spring of 1996 and a third sample of students enrolled in a course on sleep and dreams in a classroom setting, who took the on-line dream course as part of the Sleep and Dreams course requirements. This third sample provides a link between the purely classroom students experience and the experience of the purely on-line student.

The Introductory Psychology students were 16 males and 15 females almost half of whom English was not their first language (48%). A bit more than a third were Asian or Oriental with slightly less than half of European ancestry. Most of the students were in their 20's with 39% being first borns or only children. The beta students volunteered to participate in the course through informal networks of the author/instructor. Although 43 registered, only 26 completed the first assignment, 12 of the 16 registered males and 14 of the 27 registered females. Their average age was mid-40's with 65% first borns or only children. Most were employed full time. The vast majority (88%) spoke English as their first language and 81% were of European ancestry. Finally, the majority of the students enrolled in Sleep and Dreams were female (n=23) with only 8 males in the class. These students were also in their early 20's with as many first borns or only children as later borns. English was their first language for all but one of the students while three were of non-European ethnic background. It can be seen that in addition to receiving the course materials in very different settings, these three groups of people are different in other ways.

Questions that all three student groups answered included demographics (sex, birth order, first language, and ethnic background) and questions about their sleep and dream habits (had they ever kept a dream diary, hours of sleep, and dreams recalled per month). They were also asked the degree of importance of religion in their lives. An abbreviated version of the Dream Response Questionnaire (DRQ) was also included in the questionnaire/assignment. This is scored along eight dimensions of attitudes towards dreams. For the on-line version of the questionnaire information regarding items belonging to subscales was available for the student as they took the questionnaire while it was not available for the Introductory Psychology students who took the questionnaire in a paper and pencil form during class. This shortened version of the DRQ was scored as a function of subscales and a total scale score. The subscales were Insight, Discuss, Spiritual, Leisure/escape, Vivid imagery, Reject, Author/style, and Storydriven.

Results/Discussion

The information available on the three samples of students was classified into two types. Variables which represent the characteristics of the student and those which may have been affected by the course material (in reading/lecture). The first set of variables included sex of subject, birth order, first language, ethnic background, dream diary history, importance of religion, hours of sleep per night and dreams recalled per month. The scores on the DRQ subscales and full scale score constitute variables which reasonably may have been affected by the content of the material on dreams.

As mentioned above the three samples of students varied in a number of ways besides their course enrollment. Therefore a varimax factor analysis was calculated on the subject characteristics in order to determine which variables covaried with sample. Sample loaded most strongly on the first two factors. Specifically, on the first factor the more electronic the presentation the higher the dream recall per month and the more likely the student was to have kept a dream diary. The second factor showed that electronic presentation was associated with English speaking European ancestry in females. Based on this analysis dream recall, sex of subject and language/ethnic background were controlled for in all subsequent analyses in a variety of ways. All students with non-European ethnic background who did not speak English as their first language were deleted. This left 63 subjects; 15 from the Introductory Psychology class (no electronic component condition), 28 from the Sleep and Dreams class (both electronic and classroom condition) and 20 from the Beta class (all electronic presentation condition).

Dream recall was controlled by using it as a covariant in all subsequent analyses. Number of dreams recalled per month was used rather than history of keeping a dream diary as the former is more sensitive to individual differences than the yes/no response category used for dream diary history. Sex of subject was controlled by using it as a between subject variable. This is further justified by the strong precedence in the dream literature for consistent sex differences in dreaming attitudes and styles. By controlling for the known covariants in these ways findings from comparisons between samples/conditions can be said to more closely approximate differences in presentation of the material rather than group content differences.

Nine analyses of covariance with two between subject independent variables (sex of subject: male and female; condition: no electronic presentation [Introductory Psychology], some electronic presentation [Sleep and Dreams] and all electronic presentation [Beta class]) were then calculated on the scores of the eight subscales of the DRQ and on the DRQ sum score. In all cases high scores indicates a positive attitude towards dreams. There were no main effects or interactions with dream recall controlled for the ANCOVA's calculated on Leisure/escape, Rejection, Insight, Storydriven, Discuss and Vivid Imagery subscale scores.

A significant main effects occurred in the ANCOVA for Author/style while those for Spirituality and for the DRQ sum score analyses approached significance. For the Author/style analyses a main effect for condition (F(2,49)=3.76, p=.03) occurred. Students in the electronic condition/Beta class (mean=3.25) were significantly more likely to be sensitive to the dreams style of story telling than the mixed media class (Sleep and Dreams; mean=2.63) but did not differ from the nonelectronic presentation (Introductory Psychology; mean=3.03) students.

The other subscale to result in near significant condition differences was Spirituality. Here the sex by condition interaction approached significance (F(2,51)=2.569, p=.0865). It was the males in the nonelectronic (Introductory Psychology) condition which accounted in the main for the interaction. Specifically they were considerably less likely to report using their dreams for spiritual purposes than all other students who reported moderate usage. The final ANCOVA was on DRQ sum scores. The condition main effect without dream control approached significance (F(2,48)=2.556, p=.0881) such that the mixed condition students had the lowest sum scores, although Fisher's a-postori test resulted in no group differences (Introductory Psychology mean=24.9; Sleep and Dreams mean = 24.796; and Beta Class mean = 24.944).

In conclusion, since the only unequivocal finding was for one of the nine DRQ dependent variables while two showed marginal results, it must be concluded that style of presentation does not in general affect the outcome of the impact of material on the students at least in a dream course.

SAMI (C-L2): Development and Evaluation of a Multimedia Cooperative Learning System

Lucie Gagnon
G.R.A.I.M.

Université Laval
Québec, Canada
allaroy@qbc.clic.net

Abstract: We have developed two prototypes of a multimedia learning system. The first prototype is designed specifically for cooperative learning. It includes various strategies which may enhance interactions between two students working at the computer. The second prototype includes only features that are recommended for cooperative learning, but that could also be found in multimedia systems designed for individual learning. The content of both of these learning systems is based on oral and written comprehension objectives drawn from the ESL (English as a Second Language) curriculum for grade 5 students. Interactions between students will be monitored in order to determine the type and number of interactions generated during the different activities. This project is the subject of a doctoral thesis supervised by Professor Philippe Marton.

1. Theoretical considerations

Cooperative learning involves learning in groups through structured activities designed to improve learning through the development of social skills. The verbal activity taking place between team members, particularly asking for and giving explanations [Webb 1985], seems to play a role in improving performance. "Learning Together" [Johnson, Johnson and Holubec 1993] details several elements that are fundamental to a cooperative learning environment. In the field of language education, a few studies [Chang and Smith 1991] have been conducted concerning small group learning at the computer. In those studies that did attempt to give a certain structure to the activity, the structuring was always done from outside the computer, via verbal or written instructions. It seems that grouping students according to sex [Johnson, Johnson and Stanne, 1986] and ability may affect the type and the number of interactions between team members [Hooper and Hannafin, 1991].

2. Development

The content objectives deal with the identification and the description of an animal, object or place in ESL. They are concerned with the comprehension of oral and written output. Students enter the forest in which they meet two people; a forest ranger and three campers. If they choose to meet the forest ranger, he will ask them to help him find three birds. Several strategies have been devised in order to comply with the elements put forth by the "Learning Together" method of cooperative learning. Most of the strategies aimed at fostering *positive interdependence* are included in both prototypes since these strategies would be part of virtually any learning system. All the other strategies are included only in the cooperative prototype.

Elements of "Learning Together"	Strategies (example)
positive interdependence	
ñ outcome interdependence	
goal interdependence	ñ finding the bird
reward interdependence	ñ receiving a badge if the bird is found
ñ means interdependence	
resource interdependence	ñ using pictures, notebook, glossary
role interdependence	ñ controlling the keyboard, reading
environmental interdependence	ñ working side by side at the computer
ñ interpersonal interdependence	
face-to-face promotive interactions	ñ recalling cooperative behaviors at regular intervals
individual accountability	ñ individual testing at the end of each section
interpersonal and small-group skills	ñ video segment of two groups of two students working together ñ suggesting cooperative behaviors regularly
group processing	ñ asking the team at regular intervals to evaluate its use of the social skills previously suggested

The two prototypes were developed using Toolbook 4.0. An evaluation of both prototypes has recently been conducted with four groups of two grade 5 students. This was helpful in verifying that the systems ran smoothly, that the instructions were easily understood by students and that they felt at ease with the learning systems. A second evaluation of the prototypes will be conducted in the next few weeks. This phase will be concerned with the type and quantity of interactions generated while teams are using the two learning systems and the time and number of attempts required to complete both activities. Twelve teams of two grade 5 students will take part in this phase of the evaluation process. Students will be grouped according to their sex and their ability level. Teams will be videotaped and each member will be interviewed individually during a semi-constructed interview which will immediately follow the activity at the computer. Three observers will review the videotapes using a grid to record the type and the quantity of interactions generated.

3. Conclusion

The originality of this research resides in the fact that the cooperative learning situation will be structured from within the multimedia learning system. With this qualitative research, we hope to generate hypotheses that may be useful in future research concerned with the development and use of multimedia cooperative learning systems for various learning contents and populations.

Neuroinformatics at the Secondary and Post-Secondary Levels of Education in Lithuania

Algis Garliauskas
Neuroinformatics Department,
Institute of Mathematics and Informatics,
Akademijos 4, 2600, Vilnius, Lithuania
E-mail: galgis@ktl.mii.lt

The traditional informatics is based on the paradigm of sequentional computations to evaluate functions and soliutions. Today wider and more complex notions are necessary. The computer is to be seen as a component in a distributed, interactive systems of human, machines and other artificial and natural dynamic systems such that a paradigm of a group of communicating individuals will be more adequate. In particularly the areas of artificial intelligence and artificial neural networks are considered to be subareas of informatics. Therefore the neural computational linguistics and cognitive science are very important for engineering, communication theory and informatics as well as for education processes at the secondary and post-secondary levels. The main aim is to give knowledge for pupils and students about informatics: neural models, neural networks, parallelism in computing, learning with/out superviser and recalling, introduction in neuroinformatics, neural network software applying in different practical areas.

The main objectives of this activities are following:

a) to introduce a new area of informatics, i.e., neuroinformatics for older classes of Lithuanian secondary schools and university students as well as in other Baltic Countries;

b) to create simple with high visualization education neural network software and to promote it in practical classes of the secondary and post-secondary levels of education;

c) to use widely the computer-electronic networks for education process together with new ideas of informatics.

Reverse Engineering the Computer Graphics Animation and Multi-media Job Market: A Fine Arts Curriculum for the Digital Age

Gregory Patrick Garvey
Department of Design Art
Concordia University
Montreal, Quebec, CANADA
ggarvey@vax2.concordia.ca

Abstract: This short paper argues that a fine art and design education coupled with "digital literacy" is not a costly frill but rather is essential preparation for the job market shaped by the global economy. The skills of the artist and designer once thought to be marginal to business success now have taken on a new importance as an integral part of the multi-media revolution as seen in the rapid growth in computer graphics animation, interactive multi-media and design for the World Wide Web. A major study sponsored by Human Resources Development Canada entitled *Shaping Canada's Future by Design* promotes design as prerequisite to entering the marketplace and calls for significant changes in how design is taught especially in regard to the acquisition of managerial and business skills. This paper describes how the new double major in Computer Science and Fine Arts under the Digital Image/Sound Programme at Concordia University answers this challenge.

In Canada and in Quebec the "lean and mean" trend toward "downsizing" has impacted not only the corporate sector but has led to dramatic and deep cuts in funding of higher education at both the federal and provincial levels. As the baby boom generation ages universities are forced to compete for a smaller pool of potential college age customers within the borders of province and country. The "globalization" of higher education, due in part to increased mobility across borders of potential "customers" made possible by short term educational visas, distance education strategies and the exploitation of the internet for education has forced universities to compete internationally. The law of supply and demand of the new global educational marketplace along with diminishing budgets have forced universities to re-consider and revamp the traditional curricula leading in some cases to wholesale closure of programmes and departments. Students demand programmes that will get them jobs. The distinction between a university education and vocational training appropriate to the college level is blurred. At first glance programmes in fine arts and design would appear to be irrelevant to the job market and thereby vulnerable to the cost /revenue ratio meat cleaver.

The rapid growth in fields such as computer graphics animation, interactive multi-media and design for the World Wide Web is not dependent on technology alone. The role of the artist and designer must not be overlooked as an essential part of the multi-media revolution. Once thought to be marginal to business concerns the artistic qualities and design attributes of a web site or a consumer product provide the competitive edge that determines success in the marketplace. A major study sponsored by Human Resources Development Canada, entitled *Shaping Canada's Future by Design* [Price Waterhouse 1997] quotes John Tyson, Vice President Corporate Design, BNR (1994): "Design, now, is nothing less than table stakes. It is not even a competitive weapon. It is the cost of entry into the global market." This report calls for significant changes in how design is taught especially in regard to the acquisition of managerial and business skills. Art and design education coupled with "digital literacy" is not a costly frill but rather is essential to prepare graduates for the job market shaped by the global economy.

The World Wide Web is perhaps the best example of the importance of art and design. Successful web page development depends on the traditional skills of a writer, art director, graphic designer, typographer,

BEST COPY AVAILABLE

illustrator/painter/photographer in combination with the newer expertise of the 2D & 3D animator, videographer, programmer, composer, sound effects designer, cognitive psychologist and a human factors engineer. In feature film production and animation the importance and the extent to which traditional fine arts skills are integrated into the digital job market can readily be seen in the job descriptions. PIXAR the makers of *Toy Story* look for computer animators who have an "All-Around Art Background: Life drawing, sculpting, painting, etc." Speilberg's DREAM WORKS ANIMATION recommends that potential candidates include "Pencil life drawings; rough sketches of animals and humans in movement; samples of personal work to show your color and design abilities." SONY PICTURES IMAGEWORKS requires the following qualifications: "Previous experience as a storyboard artist, with sketching and rendering skills on a Mac or SGI platform, using Photoshop or equivalent. Excellent client presentation and painting skills highly desirable. Bachelor's degree in Art." George Lucas' INDUSTRIAL LIGHT & MAGIC advises job seekers "to have a good educational and/or professional blend of computer knowledge and artistic studies."

In the Fall of 1997 Concordia University in Montréal begins a new programme offering the Major in Digital Image/Sound and the Fine Arts in conjunction with the new Option in Computer Science: Computer Applications. This programme includes a minor as well that provides an educational "blend of computer knowledge and artistic studies." This is not a vocational programme where a student receives accelerated application specific training over a 10 month period. This university level programme offers an in depth technical and artistic education requiring 45 credits in computer science and 45 credits of fine arts courses leading to the Bachelor of Science degree. Course requirements include software engineering, and multi-media authoring balanced by electives taken in the studio arts.

I have argued previously [Garvey 96] in regard to studio art electives and the experimental use of multi-media that the appropriate pedagogical approach calls for what might be called "user centered education." This is best achieved by the self-directed process of discovery through learning by doing combined with collaborative learning between teacher and student and between the students themselves. "In design or in fine art this means the student defines aesthetic goals and follows his or her own personal tastes and expression." The identification of the "digital arts" calls for a re-alignment and exploration of intersections across a number of disciplines previously separated by department and faculties including Commerce and Administration.

A broad based in depth "digital literacy" in a fine arts context is achievable by the careful and selective introduction and organization of a sequence of projects that combine technical and aesthetic problems over the span of three to four years leading to the Bachelor of Fine Arts. This is by necessity a multi-year interdisciplinary programme, guided by the dual principles of "learning by doing" and "user-centered education" in an environment of structured collaboration. The assertion of these intersections acknowledges the complexity of human behavior and is motivated in part by Howard Gardner 's theory of multiple intelligences where he identifies seven intelligences: linguistic, musical, logical-mathematical, spatial, bodily-kinesthetic, and the personal intelligences–intra personal [Gardner 1983]. Such a curriculum design should also take into account Donald Norman's identification of the stages of complex learning and Seymour Papert's assertion that the computer should be thought of as a material with which one constructs. "The final goal is to encourage students to learn how to learn, how to teach themselves to analyze and define problems and how to find solutions through self created tools." [Garvey 1995]

THE ROLE OF EDUCATIONAL TECHNOLOGY IN THE UKRAINE AND THE PHILIPPINES: TWO CASE STUDIES

Clark Germann
Associate Professor, Technical Communication

Sharon Siverts
sivertss@mscd.edu
Provost and Vice President for Academic Affairs

Metropolitan State College of Denver
PO Box 173362
Denver CO USA 80217-3362

Abstract: This paper describes how Metropolitan State College of Denver is using technology in working with institutions of higher education in the Ukraine and the Philippines. The examples describe two different environments in working toward effective use of educational and distance learning technologies.

Global education that prepares our students to live and work in a worldwide community has long been the promise of distance and educational technology. Until recently, however, that promise languished because of an inadequate international technological infrastructure and a lack of understanding and often reluctance on the part of educators to use that technology. Bailey and Cotlar (1994) write, "Resistance to pedagogical changes utilizing technology is often due to faculty and administrator reluctance to explore new techniques out of a fear of change in general or the technology in particular." This resistance is slowly lessening, and the widespread implementation of the Internet is resolving technological issues. Recently, faculty and administration at Metropolitan State College of Denver (MSCD) have had experience in serving remote and developing areas of the world from policy study and development and practical instructional applications.

MSCD, located in Colorado, is the largest public undergraduate urban institution in the U.S. The college has made a significant commitment to the teaching/learning paradigm and to the use of appropriate technology to increase access and student learning. MSCD recognizes the important role of internationalism. The authors report on how technology is allowing MSCD students to interact with their counterparts in Crimea, Ukraine; and how it is being used in the Philippines to help educators think and act strategically in the development and implementation of policies to meet defined goals.

Ukraine

Since 1994, faculty from MSCD and a partner institution have been working with Simferopal State University in Crimea, Ukraine to provide opportunities for students in both countries. More than 50 Ukrainian students and 200 U.S. students have participated in the project. Simferopal State University is located in Simferopal, a major population center of Crimea, Ukraine. The university serves some 5,500 undergraduate and graduate students and is well known for its curriculum in theoretical physics. Progress to date includes:

--Online courses--Ukrainian students have completed some of the online courses currently being offered by the U.S. schools. If space exists in a class, and with instructor permission, the students are allowed to participate. Ukrainian students are often paired with US students to work on course projects. In addition, they are usually included in e-mail groups to discuss course readings and assignments.

--Course resources--researchers have long espoused the availability of resource people located throughout the world as a major advantage of distance education (McComb, 1994). Ukrainian students not participating in formal online courses, as well as their professors and advisors, are often available as

BEST COPY AVAILABLE

primary resources to US students. Input from the Ukrainian students is valuable in virtually all courses, not just those dealing with Ukraine and Eastern Europe.

Ukrainian students in this project have access to only one Internet e-mail account, and messages from MSCD instructors and students are printed and distributed individually. Despite this limitation, the system has been remarkably reliable with very few messages being lost during a two year period. More restricting is the fact that the students have access only to e-mail--other Internet functions, including access to the World Wide Web, are not yet available. Students and instructors at both institutions have been remarkably clever in encoding binary files into e-mail messages, but the true potential of this project will not be realized until other Internet functions become usable.

The Philippines

The Philippines, a developing country, has a goal of being internationally competitive in the next century. The country's leadership recognizes the importance of global connectivity. The Commission on Higher Education CHED) is a newly created national agency responsible for the approximately 1,200 public and private higher education institutions in the country. Over the past two years, the Commission has been developing a long term development plan for higher education in the Philippines.

The needs and challenges are many. Clearly, technology is one. Technology can help advance the country's goal of global competitiveness; technology can assist in developing a national infrastructure for data collection; technology can build and enhance research capacity so needed in a developing country; technology can enhance learning and teaching and provide opportunities for students and faculty throughout the world to interact and solve real world problems; and technology can improve access. Technology relates directly to each of the four priorities of the Commission: quality and excellence; relevance and responsiveness; access and equity; and efficiency and effectiveness.

While the Commission recognizes the importance of technology, the main office in Manila has no connectivity. Fourteen regional offices report to the central office; none have computer connectivity. These offices oversee hundreds of institutions and thousands of students, yet there is no database from which to work.

Yet, some of the private institutions and a few of the public institutions have the infrastructure in place and are competitive. Internet access is not a common feature either at CHED or at many of the institutions throughout the Philippines. Thus, key issues relate to resources for infrastructure, equipment, and faculty and staff training in order to provide an environment for higher education to adequately prepare students for the global market.

Conclusion

These two examples describe two different environments in two developing countries, one from a practical level and one from a policy level in working toward effective use of educational and distance learning technologies. Initiatives like these are only the beginning. Dubois (1996) writes "For years the distance learning community has patiently awaited a global education mandate which advocates multidisciplinary learning, global awareness, foreign area and multicultural studies...After all these years, we now have a sense of urgency, a curricular focus, and a national initiative." As more and more educators work towards true global education, we may begin to realize the dream of Marshall McLuhan for a "global village."

Abstract: The purpose of this presentation is to report some of the results from our efforts to come to a better understanding of the learning that occurs while subjects are using a particular piece of instructional software. Relying on the dense and rich data available through verbal protocol analysis has led to some interesting insights over the course of this project. We describe these results and stress the importance of exactly this sort of fine-grained analysis of learning behavior for improving the positive impact of technology in educational settings.

This paper summarizes results from the first step in a multi-stage project to test the applicability of the ACT-R theory [Anderson 1993] as a foundation for modeling cognitive skill acquisition with a tutoring system *not* developed by CMU's Advanced Computer Tutoring Group [Anderson, Corbett, Koedinger & Pelletier 1995]. It is the first time such an effort has been undertaken.

The tutor chosen for this project is the *Data Organization and Plotting Module* [Shute & Gluck 1994] of the *Stat Lady Descriptive Statistics Tutor*, developed at Armstrong Laboratory's TRAIN Lab. It is designed primarily as a cognitive modeling research platform [Shute 1995], but has also demonstrated real value as educational software that results in significant learning gains [Shute & Gluck 1995].

The first step in developing a cognitive model of how students learn from *Stat Lady* was to study student-tutor interaction at a fine level of detail. We ran four verbal protocol subjects at CMU through the *Stat Lady* pretest, tutor, and posttest. These subjects provided concurrent talk-aloud protocols [Ericsson & Simon 1990] the entire time, which averaged a little more than 8 hours of participation per subject. Subjects were prompted to talk aloud at all times, resulting in dense verbal data on their interactions with the tutoring system. Due to the impracticality of analyzing the entirety of the verbal data, we identified the easiest and hardest sections of the tutor and focused the protocol analysis there. Those two sections comprise 40% of the time spent on the tutor, and are the 1st and 3rd of five sections. For reliability, a second experimenter independently segmented and coded half of each subject's protocols. Perfect coding agreement was reached on 89.8% of 3,266 protocol segments. Codes for the remaining segments were easily agreed upon after brief discussion.

As is the case in any tutor development project, various implicit and explicit assumptions guided the creation of *Stat Lady*. Attending to subjects' learning and performance behaviors at such a fine level of detail with this rich set of verbal data has allowed us the opportunity to examine how students actually use the tutor, as well as what and when they really learn from it. In other words, we have put some of the design assumptions to the test.

Testing the Design Assumptions

The tutor is sub-divided into five main topic areas, each one building to some degree on the material covered in the earlier areas. The pedagogical pattern within each topic area is (1) an instruction section which presents relevant material and gives the learner an initial chance to apply that knowledge in problem solving, and (2) a set of scenarios which test the requisite skills. The student chooses one scenario at a time from a set of five, based on personal interest (e.g., football, amusement park). Each scenario begins with a story that establishes a "context" and related goal, the pursuit of which requires the student to answer questions and perform tasks relevant to the curriculum objectives. Responses during all problem solving activities are accompanied by positive and negative feedback in both text and sound file formats. Rather than stoically functional in character, some effort was invested in developing feedback that reflected the personality of *Stat Lady*, which is perhaps best described as "sassy." The assumption in creating the elaborate feedback and detailed contexts was that this would draw students into and keep them involved with the learning process. In fact, there is evidence in the verbal protocols that this is the case. Almost without exception, the participants in this study read the context portions of each scenario very carefully, often reflecting aloud on the plot or premise of the scenario along the way. This is despite the fact that knowledge of the context is not absolutely essential for successful completion of the scenario and it is possible to skip right past it without much more than a cursory glance. Second, there are examples throughout the protocols of students reacting to the feedback sound files, sort of "talking back" to the tutor, as if receiving feedback from a human. This suggests that those sound files may help maintain a higher level of student involvement in the tutorial process, but this remains an empirical issue.

A second significant assumption influencing the design of the tutor, and which is consistent with contemporary learning theory, is the assumption that most of the knowledge and skill learning comes with opportunities to practice and apply those skills. In the case of this tutor, the assumption was that those opportunities would come primarily during the scenarios. Our protocols indicate that significant learning events often are taking place well before the scenarios - in the instruction section, and sometimes even in the pretest. Information like this is important to know for those interested in maximizing efficiency via student modeling.

A final design assumption was that providing a certain degree of redundancy in the instructions for working through problems and in the feedback (note that they receive both auditory and text feedback) would facilitate more effective and efficient learning by reducing the need for search across the screen. Thus, if a subject is not sure what to do next, it is often the case that the directions can be found in more than one location on the screen. Verbalization trends from our protocol subjects suggest a sensitivity to which portions of the screen are important for problem solving at any particular time. Less important (mostly redundant) sections of the interface are attended to less and less with practice. This indicates a facility for acquiring knowledge of the structure of the learning environment, and that students become sensitive to this structure and adapt their behavior accordingly.

The Take-Home Message

What lessons might other designers of educational research software extract from these conclusions? First, consider interesting auditory feedback and problem solving contexts as means of maintaining student involvement in the learning process. Second, allow for the possibility of early learning events, especially when designing tutors that will include student modeling capabilities. Third, it may be important to build cognitive models of not only the learning of the specific curriculum objectives the tutor is designed to teach, but also the acquisition of environment/interface knowledge. Finally, and most importantly, we strongly encourage developers of instructional software to invest some time in this sort of close analysis of student learning with their systems. As evidenced here, there is a very real potential for interesting insights.

Peitho: a Support Tool for Learning Critical Thinking

Dr. Dave Goforth, Department of Mathematics and Computer Science
Laurentian University, Sudbury, Ontario, Canada
goforth@ramsey.cs.laurentian.ca

Abstract: This paper describes a software tool called Peitho that supports critical thinking and, particularly, the learning of critical thinking skills. Peitho uses a rhetorical rather than logical model to represent knowledge about critical thinking. While this model is flexible and broadly applicable, it is shallow in that the meaning of the content of an argument is only represented in text overlaid on rhetorical structures. This apparent step backward from knowledge representation shifts the burden of domain expertise to the user. However, Peitho, as rhetorical expert, can still offer advice on analyzing content. Applying Peitho to particular models used in teaching critical thinking has revealed weaknesses in those models and has lead to a taxonomy of features for judging particular instructional models of critical thinking.

Theoretical Model

Peitho is a generic argument design system. Within it, templates are created to fit a specific domain, such as law or science, or to match the strategies of a particular textbook on critical thinking. These templates are then used to construct or critique arguments. As described later, the creation of Peitho templates is a rigorous and revealing test of models of critical thinking.

Critical thinking is the skill of rational persuasion. It is the ability to frame an argument to persuade others and the ability to decide how much to be persuaded by the argument made by someone else. As such, critical thinking is more than just logic because one can persuade where formal proof is not possible. Conversely, critical thinking is less than rhetoric with its three modes of persuasion: *logos*, *ethos* and *pathos*. Critical thinking comprises only the rationality of logos, rejecting the appeal to emotion of pathos and the appeal to authority of ethos.

How then to represent the reasoning process in a program to support the learning of critical thinking? Critical thinking is not restricted to formally constructed domains so the choice of a representation system must consider this constraint. Logic *has* been extended to embrace the incomplete and inconsistent information which is characteristic of common sense reasoning but the resulting constructs are not very powerful and not very intuitive. There are also credible alternative representations like neural networks and genetic algorithms which handle messier problems quite well. Unfortunately, these non-symbolic systems do not provide much meaningful structure from which a human observer can learn.

Rhetorical models retain the symbolic representation of logic and are more accommodating of incomplete and inconsistent information. Indeed, a rhetorical argument is typically presented in a situation of dialogue in the full expectation that it will be challenged. Such models are robust and broadly applicable. Most texts on reasoning and critical thinking include a model of this type, identified as 'informal reasoning.'

The major drawback of these informal models as a basis for software is that they are representationally powerful but procedurally weak: they can describe argumentation but they can't 'do' argumentation the way logic or neural nets can. In spite of this, Peitho was designed as a rhetorical model and turned out to have some procedural power.

A second problem with rhetorical models is that so many exist. Virtually every author on critical thinking develops a new model with unique features and emphasis. Even prominent thinkers in rhetoric, such as Toulmin [Toulmin et al. 1984], are widely acknowledged but not applied. No definitive model has emerged, so Peitho has been designed as a generic lower level environment in which particular models of reasoning can be constructed as templates.

System design

The Peitho environment is simple. An **argument** is a collection of **statements**, one of which is a **claim**. The rest of the statements are **facts** which support the claim. With the argument as justification, the claim becomes a fact to use in other arguments. Every fact should be established, either by a supporting argument or by an external **reference**.

A collection of arguments connected by claims-become-facts is a **chain of reasoning**. The claim of the final argument, called the **major claim**, presumably is the statement the arguer wishes to establish.

On this generic base, particular models of reasoning are constructed by specifying (i) what kinds of external reference are acceptable and (ii) what the internal structure of an argument can look like. For example, Toulmin's model of argument includes, in addition to a claim, particular fact types called *backing, warrant, grounds* and *rebuttal*. (Toulmin's *modality* is a property, not a fact.)

Once the reference types and argument strategies of a particular reasoning model have been incorporated - by a course author or instructor in an educational setting - the system is ready to apply to critical thinking in some domain of knowledge. This is the student activity in an educational setting.

To support the arguer, the structural model is complemented by a process model defining three activities, (i) **information gathering**: statements are added to the set, (ii) **organization**: the statements are assembled into arguments to form a chain of reasoning, and (iii) **analysis**: the reasoning is critically examined for structural and semantic validity. The user shifts easily but explicitly among the activities.

At the analysis stage, Peitho supports the user in critiquing the chain of reasoning. First, it does automated analysis based on the generic structure. For example, circular reasoning can be identified as a cycle in the chain of reasoning graph. Second, it includes an advising feature inspired by the observations of writing instructors that, even without domain knowledge, they can successfully advise learners. [e.g., LeBlanc 1993] The generic structure contains some advice, for example guidance on examining individual statements for ambiguity. More specific advice about particular argument templates is provided by the template creator. Advice is context sensitive: the learner is reminded of requirements at a particular point and guided to evaluate statements and structures by applying her own domain knowledge.

A payoff - Rigour in Models of Critical Thinking

Peitho currently exists as a prototype system in Visual Basic. The instructor of a philosophy course on *straight thinking and argument* has used the software to construct templates and confirmed that it successfully captures the particular approach to critical thinking which he uses. The system has also been used by experienced critical thinkers to develop and criticize arguments but has not yet been tested with learners as the user interface is being improved.

Nonetheless, Peitho has already proved its usefulness in an unforeseen way. During development, many models of critical thinking were examined and had influence on the design but the fact that none stood out as exemplary led to the generic low level model that was finally adopted. To test the software, the models were implemented as Peitho templates. This was a rigourous test that exposed the strengths and weaknesses of each. Some models contained incorrect features but most just suffered from an imbalance of emphasis - authors stressed aspects they considered important and ignored others. From this experience, we propose some features essential to a complete model of critical thinking for instructional use:

- Does the model allow for differences among domains of discourse?
- Does the model define the dependence of arguments on backing from the domain?
- Does the model define properties of statements or atomic units of information?
- Does the model define both structures of argument and processes of argumentation?
- Does the model account for one step arguments and extended chains of reasoning?
- Does the model decompose in a learnable manner?

The CD-ROM version of this paper contains more detail on Peitho and the meta-model of critical thinking.

Abstract: In this paper, we are going to consider a parallel analog network which is dedicated to video and which works together with the regular digital network. This approach can be very efficient for those applications which require the distribution of full- screen real-time motion video to many users simultaneously. Video distribution via separate analog network will not affect the digital part of the network and, hence, can be used for different real-time class activities without slowing down data processing through the digital media. We used ADViNet for all traditional classroom activities: lectures, tutorials, group work, and class monitoring. A specially developed adaptive feature of the ADViNet allowed us to provide very efficient class monitoring during drills as well as real-time help to the students who have difficulties.

Introduction

Computer networks and data communication technology have had a profound impact on education. Networks can dramatically improve the teaching and leaning environment in the classroom [Ahamed 97]. Different educational network-based systems can benefit from presenting full-screen real-time motion video to many users simultaneously. Desktop video is a technology struggling to cope with two major challenges in the transmission and management of digital audiovisual data: the large amount of data involved and the time-dependent structure of the information. The first challenge requires large storage capacity and a high rate of data transmission. To meet the second challenge video information must be delivered on time. Video is known as delay-sensitive payload [Goldman 95]. A typical LAN is inefficient when transmitting large continuous blocks of data. When the network becomes busy, all real-time data including video will be slowed down.

A variety of strategies can be used to improve video distribution in LANs ["The Challenges of Networking Video Applications" 96]. Among them are: the replacement of bottleneck equipment and protocols, the installation of faster transmitting media, a change of the topology of the network which better fits the purpose of video distribution (changing from bus to star topology), the use of compression, and the installation of parallel equipment dedicated to video distribution. In this paper, we are going to consider a parallel analog network which is dedicated to video and which works together with the regular digital network. This approach can be very efficient for those applications which require the distribution of full- screen real-time motion video to many users simultaneously (broadcasting or multicasting). Video distribution via separate analog network will not affect the digital part of the network and, hence, can be used for different real-time class activities without slowing down data processing through the digital media.

Hybrid Analog/Digital Video Networks (ADViNet).

The typical physical architecture of ADViNet includes two communication media: digital and analog. The digital medium is used by the regular digital network according to its type and topology. The analog medium combines a VGA bus with several additional control lines. All the monitors in the LAN are connected to this bus by special switches. Each monitor can work in one of the two states: local - when the user can work independently with his\her workstation; and remote - when the monitor is connected to a remote source of video information. The analog bus is controlled centrally from the master station We developed a logical architecture of the ADViNet. On the logical level, any station in the ADViNet can be active; for a limited time, any station can have the status of the master station in the control of the analog medium. An ADViNet with this architecture is able to support not only single presentations, but also different kinds of network jobs where all the participants may be active. These activities and group work can be held concurrently with other network actions and will not slow them down. Any real-time graphical information including motion video can be presented in the full-screen format. The analog medium is controlled through the digital part of the network. In order to move to a decentralized model, in which any station (under certain conditions) can control an analog network, a two-layer ADViNet management protocol was developed. The physical layer provides a set of the necessary protocol commands to control the analog part of the video network. These commands are hardware oriented. They depend on the type of the hardware and, among others, include all the commands that can be issued to the analog network in the manual control mode. All the commands on the physical layer can be issued only from the master station. The main function of this layer is to support the programming control of the analog video network from the master station. Introducing the physical layer of the ADViNet management protocol does not change the architecture of the video network: it is still a network with centralized control.

The logical layer of the ADViNet protocol does not depend on hardware. This layer allows us to transform a video network with centralized control to a decentralized model. Any workstation which intends to control a video network has to open a session. To accomplish this task, the workstation should send an appropriate request to the master station. If the session can be opened, the parameters are negotiated. For all communications on the logical layer, both a workstation and the master station use a regular digital network.

Network management software includes the following functions: session establishment and control, administration, analog network monitoring, security, statistical analysis and reports.

In a multicast mode, the video images are transmitted from one station to a group of stations. Very often this group cannot be defined in advance. The set of nodes included in the group can even be changed during the session. As a consequence, the analog video network is capable of reconfiguration on the fly to meet changing needs. For this, we included extra computational capabilities in the ADViNet protocol. Specially developed protocol primitives enable a primary station to have dynamic control over the states of the secondary stations. This was done by providing the computation and analysis of several functions that depend on students' performance and define whether or not to include a student station into the group. Such a video network will change its configuration dynamically, as needed, in response to random external events.

Teaching in the ADViNet Environment.

We used ADViNet for all traditional classroom activities: lectures, tutorials, group work, and class monitoring. On the hardware level, the network is based on Computer Video Web (ComWeb) from ComWeb Technology Group, Inc ["Computer Video Web" 96]. ComWeb is a pure hardware system which provides physical connections (36 workstations and one master station in our classroom) and the ability to control the video network manually (by using the Control Panel). The main system hub has a special port that enables the master station to control a video network remotely by using a serial interface.

One of the goals of this network is to enable the instructor to analyze the students' performance and provide them help in real time. A specially developed adaptive feature of the ADViNet allows to provide very efficient class monitoring during drills as well as real-time help to the students who have difficulties. For this purpose, the master station gathers and analyzes the information about the current state of any student's station. This information shows each student's performance. Based on the analysis, the master station dynamically changes the configuration of the ADViNet: new nodes can be added to the monitored group, and others can be removed. The instructor can always observe only those students who are behind the schedule and submit them real-time help by taking control over their computers.

From our experience, we can say that video networks prove to be very helpful in the classroom and have considerable influence on the teaching methodology.

Abstract

The Child Development Observation Resource (CDOR1) CD-ROM provides a learning environment for practice and experience in observation methods for students studying education, psychology, and related professional courses. Observational analysis requires theoretical understanding and practice for the development of the skills of coding. The CDOR1 multi-media environment is designed to afford students the opportunity to learn about the benefits and constraints of observational methods and to engage in practice through viewing child development video clips, examining key texts, applying standard coding schemes, and developing new coding schemes. CDOR1 is intended to be suitable for use within a structured course of study, or as a stand-alone package. Evaluations conducted 'in-the-field' will further guide this work-in-progress.

1. Introduction

This paper describes an interactive multimedia package, Child Development Observation Resource (CDOR1), for learning *about* observational methods and for learning *to do* observational analysis, which is being developed at the Open University. The possibilities of using new technology to provide environments to foster the advantages of learning by doing (such as the enactment effect and the generation effect) has been well recognised (Hammond, 1993); it is intended that this package nurtures such learning. In its current form CDOR1 contains a wide range of documentary materials about child development including video of child development experiments, and video of children alone and interacting in groups. The package is particularly applicable to students of psychology, education, and social work studies.

The package aims to:

- provide training in methods of observing, coding and analysing human behaviour in natural and experimental settings
- assist students in linking research evidence with practice
- demonstrate the methods and results of key experiments in developmental psychology and other areas of social science
- give access to leading researchers' verbal descriptions of their research, its methods and theoretical implications

2. Structure of CDOR1

The design of CDOR1 is intended to be flexible enough to enable an academic teacher to draw upon the resources available in the application freely, using video, texts, coding tools, literature, and lecture sources as he or she considers best, to fit the purpose of their teaching. In addition the package is designed to support individuals who

BEST COPY AVAILABLE

are working alone and encountering such material for the first time. The application provides a tutorial level of provision, providing guidance through the media so that understanding of important concepts, such as the concept of reliability, is developed. As well as providing structured pathways, there is also the opportunity for students new to this methodology to simply view a piece of video, and to explore the images in a theoretically naive way through experimenting with the coding tools available within the package.

2.1 Training in Observational Analysis

(i) Linking Research with Practical Skill

The application contains discussions by researchers of key concepts and issues in observation and child development. It is intended that this engagement with multiple perspectives regarding observation will foster a deeper understanding (Duffy & Knuth, 1990). The package also contains a glossary of key terms and related information, as well as papers and abstracts detailing the reasoning behind the adoption of particular observation methods in the arena of child development. One option available to the students is to use the materials offered to make an informed decision regarding which coding scheme to choose, or to use the arguments advanced in key papers to construct a coding scheme of their own.

(ii) Coding Capabilities and Analysis Package

As well as allowing students to set up their own coding schemes the application contains well used and referenced coding schemes from child development studies for use by students in analysis of the video material. Students will be able to check their coding reliability against results available from expert coding.

(iii) Key Experiments

Key experiments with accompanying commentary are provided within the package. These are linked to research papers describing these studies and serve to highlight the issues and implications for observation that arise from such work.

3. Evaluation

The development of CDOR1 is currently in progress. By the summer of 1997 a beta test version of the package will be ready for evaluation within real learning contexts. It is intended that the initial context embedded evaluations will take place at Open University Summer Schools (residential components of distance learning courses) and within conventional university courses.

'Learning by doing' using new technology affords new opportunities for students of psychology and education. We anticipate that using multimedia to learn about the methods of research and the practice of professional groups will facilitate active and profitable learning for students of these disciplines.

Abstract: This session will showcase the Business Skills Online project and the technologies and strategies for teaching and learning. The Business Skills Online project migrates computer conferencing, print-based course materials to the World Wide Web (WWW). Students receive tutorial support from teachers at a distance through the use of computer technologies. In 1996-97 the Business Skills Online project is testing new ways to speed up communication between teachers and students; provide peer support and, where appropriate, achieve faster turn-around of assignments and projects. The project gives students opportunities to discover business careers in newly emerging industries and in industries often unexplored by rural remote students This session will showcase the Business Skills Online project and the technologies and strategies it utilizes for teaching and learning.

Business Skills Online: Strategies for the Electronic Environment

The Business Skills Online project is leading the way in using information technology to provide enhanced education for distance learners in British Columbia. The project offers the Open College's Business Skills courses to students in schools, learning centres, and at home.

The Open College is a service of the Open Learning Agency (OLA). Through the Open College and Open University, OLA provides accredited distance educaton programs through a variety of media.

The core of the Business Skills Online project is the mediation strategy for enhancing student success. This model involves tutor to student and tutor to group relationships as well as student to student and student to group relationships. The tutor is the content expert and instructor for a specific course and works with students from a variety of distant locations in the province of B.C.

The tutor supports students at the sites, assisting with course issues, helping with the technology if applicable, dealing with administrative issues, and providing on-going counseling. The students engage in learning activities with tutors and peers (local and distant) through computer communications technologies. They are responsible for completing their course assignments and interacting, through computer conferencing and the WWW, with tutors and other students on a regular basis. The OLA has proven that this directed independent learning model increases student completion and success rates over the duration of the project.

The Business Skills Online project engages students in learning activities directly related to the rapidly changing and competitive business markets. This program is devoted to developing solid business understanding utilizing technology, innovative communications media, and cutting edge course delivery methods.

The Open Learning Agency is committed to providing exemplary, alternative educational programs and will utilize many of the technologies, learning models, and program development strategies of Business Skills Online project to ensure success for all B.C. learners.

First Nations Distance Education: a Collaborative Approach with the First Nations of B.C. and the Open Learning Agency

Abstract: This session will showcase the First Nations Computer Conferencing project and the technologies and strategies for teaching and learning at a distance in cooperation with the Open Learning Agency (OLA). The Agency's mandate is to provide and deliver open learning opportunities in the province of B.C. We are committed to serving as a model of accessibility, opportunity, and flexibility in education. The OLA is using multi-media technology to expand its services. The First Nations Computer Conferencing project integrates computer conferencing, audio conferencing, and print-based course materials to facilitate the accomplishment of three primary tasks: course materials adaptations; professional development for instructors; and creating a virtual community for tutors and students.

First Nations Distance Education: a Collaborative Approach with the First Nations of B.C. and the Open Learning Agency

The First Nations Computer Conferencing project is developing methods of using existing technology to provide enhanced education for distance learners in First Nation educational centres. The first phase of this project connects six First Nation educational centres located throughout the province to the Open Learning Agency's Openet computer conferencing system . Future phases of the project include offering this program to other First Nation educational centres and the migration of course content to the World Wide Web.

Phase I

Course Materials Adaptations

BEST COPY AVAILABLE

Planning sessions were held with First Nations representatives to address the issue of adapting existing course materials for use in First Nations Learning Centres. Some of the items discussed were the importance that courses and materials be specific to learning centres' needs (e.g. resource management, fisheries courses). The development of aboriginal studies course materials for specific linguistic groups and adapting course material to reflect cultural needs.

Professional Development for Instructors

Through the computer conferencing system, First Nations Learning Centres are linked to the Open Learning Agency and to each other to provide a forum for sharing of ideas and solving of administrative and student issues. Professional development for instructors and tutors was one of the main focuses.

Of the key concerns voiced by First Nation Centres, the sense of frustration in the development, maintenance and support of their programs in isolation stood out. To address this issue the following items were identified as areas to base the project on:

- assignment marking - peer exception
- interaction with others for isolated instructors—share impressions of courses
- sharing experiences, problem solving, course related and matters of attendance
- counseling re catastrophic events in lives of students & community
- administrative models for setting up Adult Basic Education programs for increasing population
- coordinators ability to tap into experience of other centres in setting up and administering programs
- ongoing training for summer/seasonal replacements
- course counseling for students
- contact between First Nations instructors and regular tutors
  - interested in establishing links with non-native education centres and tutors.
- administration, promotional (student recruitment) strategies shared between centres

Virtual Community for Tutors and Students

The planning participants identified many instances where computer conferencing could be used to deliver courses to students, to link student bodies together, to enable more cost effective delivery of course for isolated students and to provide a sense of belonging to community of isolated students and tutors or groups of students.

This project enables the diverse First Nations of B.C. to form a sense of culture and community in a unique model of distance education delivered through their own learning centres.

Return on Investment (ROI) for Electronic Performance Support Systems: A Case Study

Charles H. Hawkins, Jr., University of Georgia

Abstract: Return on Investment (ROI) is defined, distinguished from Cost Benefit Analysis (CBA), and the need for ROI discussed. ROI for training versus ROI for Performance Support Systems (PSSs) is discussed as well. ROI is framed in a model developed by Kirkpatrick [Phillips 1996a], and expanded by Phillips. Several different PSSs will be used to illustrate the nature of such systems, with particular emphasis on the one supporting the Financial Management System of the Office of Veterans Affairs.

Return on Investment (ROI) is a financial measure of the value to the bottom line, of a particular investment, in this case training or a performance support system. Why is ROI needed? With a growing concern for the "bottom line", and as a potential consequence of a decreasing budget for training and other "non-direct" expenditures, return on investment (ROI) becomes an important topic in business, industry, and, more recently, government. Personnel most closely involved in human resources activities know that their work is valuable to an organization, but are not accustomed to quantifying such value in terms understandable and meaningful in today's economic climate. Developing ROI methodology provides the information needed to determine the value to the bottom line of such non-direct expenditures. This information can be used to fine tune an organization by distinguishing between services that enhance and those that detract from overall profit. Consequently, application of ROI methodology is not only a necessity for training and other human resources personnel, but also a valuable tool for budgetary decision-making in any organization. [Phillips 1996a] In some situations it may become a critical survival strategy.

Concurrently, there is growing interest in performance support systems (PSS) as a means to increase performance while decreasing training costs. Traditionally, training has been performed in a classroom or other setting external to the actual workplace. Performance support systems (PSS), on the other hand, provide assistance or training "just in time" and as needed in the workplace. PSSs have advantages over traditional training not only by providing training only when and where it is needed, but also through giving the user immediate feedback on his or her performance, distributing the training over time in the work situation and environment.

Typically, higher PSS costs are incurred during initial development. However, delivery costs are lower than for traditional training and are more difficult to track. Thus the initial ROI for a PSS is lower than the initial return for traditional training, since the learning is done "on the job". Consequently, the return on investment for a PSS increases the longer the lifetime of the PSS. However, many costs associated with traditional training, such as classroom space and travel, are eliminated with a PSS.

While the purpose of training is to enhance performance, just-in-time performance support systems are under some conditions being promoted as a better and more efficient platform for both education and performance enhancement than traditional training for many job activities, especially for those involving a computer. PSSs, however, are not a "magic bullet". There must be significant potential for performance improvement to gain significant ROI for either training or PSSs. Measuring ROI to judge the value of a PSS is just as important and needed as measuring ROI of a training program. How to perform an ROI and whether the ROI from the specific PSS being studied for this investigation is significant or not were the two major research questions of this study.

Measuring return on investment for PSSs is difficult, in that the effects often are not directly measurable. The use of control groups, one commonly used method of determining ROI for training, is not practical in most cases of PSS implementation because the consequent degraded performance for the employees not having benefit of the PSS would be detrimental to production and to morale. Additionally, there are many intangible benefits to both training and PSS. It is practically impossible to quantify the benefits of increased job satisfaction, organizational commitment, improved teamwork, customer service, and reduced stress. These qualitative benefits do have value and can be measured through survey instruments, even though that value may not be quantifiable in monetary terms.

Phillips [1996a] proposes a formula for calculating return on investment that differs from that commonly used to calculate a cost/benefit ratio. A cost/benefit ratio is calculated by dividing program benefits by program costs. Phillips proposes calculating ROI by dividing net program benefits by program costs, thereby subtracting out the cost of the program from the numerator before obtaining the final calculation.

In 1996, the U.S. Department of Veterans Affairs (VA) began a process of reorganization of education and training for employees throughout VA. In anticipation of such changes and of the paradigm shift from traditional education and training to *just-in-time*, *just-enough*, *on-demand* performance support, staff at VA's Birmingham Education Center conceptualized a new mental model, PETS—Performance, Education & Training Support—and a began series of proof-of-concept projects for developing, demonstrating, and assessing application of the model to VA's needs.

One initial proof-of-concept project addressed a critical training and performance problem for a system-wide, financial management system (FMS). The performance support solution provided the user with field prompts which appeared as clickable buttons. When clicked, a button activated a script, launching a variety of performance support assistance including standard MS Help, frequently asked questions, a glossary of terms, code tables, examples, and procedural guidance and, via a floating *flashpad*, access to the voluminous *FMS Procedural Guide*, online as converted web document.

The PSSs under development for the VA take many forms and are used in a variety of settings. Also, they continue to be refined based on experience using a rapid prototyping approach wherein incremental changes are made almost on a daily basis. Accordingly, we will illustrate several different PSSs at the Ed-Media conference, with particular emphasis on the one described above for which the ROI study is being done. Also to be described are the specific ROI model that has been developed along with its accompanying data collection tools. The model and tools are themselves being incorporated into a PSS that will be illustrated.

Abstract: This paper describes extracting attractiveness from video games in order to create attractive computer based educational system. We embed the game's attractiveness elements into educational system. For embedding the game's attractiveness, we classify the game's attractiveness based on the needed technique. This classification indicates the limitation of attractiveness realized by standard engineering techniques.

1 Introduction

To create attractive computer based educational system is important issue. Introducing game elements into educational system is well-known as one of representative approaches and therefore it is not a new idea itself. However, our idea has other new points, specially in extracting attractiveness from video games[Hayashi etal]. Video games are very popular to young people and they are known as a representative computer application with attractive elements and familiarity. The main point of our idea is to embed the attractiveness but not to implement game into educational system. Some existing educational systems include game internally. Our approach aims to provide a general way to realize an attractive system using the attractiveness elements.

2 Video game

We classified video game into eight categories; shooting game, action game, simulation game, puzzle game, adventure game, RPG (Role Playing Game), ARPG (Action RPG) and bodily sensation game.

In shooting game, players need eye sight to capture active objects and also faster reflex. If the player continues to avoid enemy attack and conversely destroys the enemies, s/he complete the game. In many cases, the player becomes a pilot of fighter and fights with many enemies in the game world such as space. Players feel the game's attractiveness in the battle. In the action game, the player can fight by body actions of her/his character. The typical world of some action games is in fantasy. This causes girls to play the action game for their own pleasure. S/he knocks down the enemy characters by her/his character operations. Simulation game are classified into types of war, board game and sports. The war type of simulation game simulates various wars and the game player behaves as a commander or samurai master. The board type and sports type of simulation game simulate various games played by some members. The computer simulates the behavior of other players except of the human player. Puzzle game requires logical thought from the game player. The player with a good logical thought is good at playing. There are some puzzle games wherein the player's thinking time is reduced and therefore s/he can play by a reflex action. There are some games which become dull after the player has completed them. Adventure game are classified into detective type and character type. The objective of the detective type is to solve some questions by inference. In the character type of adventure game, the player behaves as a character of a TV animation and so on. The attractiveness is to have experience of original world such as TV animation. The typical feature of adventure games is the quality of their scenarios, prepared by the game writer. The typical feature of RPG is growing up characters. The feature attracts the player to RPG. The characters generally grow up by experience points from the battles and the completing of quests. The player plays the game by an indirect battle simulation. ARPG is a hybrid game between RPG and action games. ARPG adopts the real time battle by direct manipulation. The player needs being skillful with her/his fingers. There are also many visual effects in the battle scene in ARPG and these effects attract the game player. Bodily sensation game includes special machine body for players to play in more real environment.

3 Game's attractiveness

We extracted various kinds of attractiveness in video games through a questionnaire. Although most of the attractiveness elements exist in traditional games without computers, high software control by the video game machine makes game's attractiveness more amusing and charming.

1267

The element of time restriction is used in many video games because computer games can easily handle the time function by using the inner timer of the computer. The time restriction excites the game player and s/he wants the excitement from the time restriction. Level up is the typical feature of RPGs and ARPGs. The game characters in these games are operated by the game player and they become to be strong by acquiring "experimental point". The characters can get the point by beating monsters or completing quests. The amount of experimental point is essential parameter for deciding the character's level. The game player enjoys bringing up her/his characters in the game's world. Stage clearing is the typical task of shooting games and action games. The world of recent shooting game is generally separated into some sub worlds called "stages." Clearing stage excites the game player so it is important as an attractiveness element of shooting game. The element of puzzle is often embedded in various kinds of games. The game player enjoys finding the answer to a puzzle in trial and error, so interesting puzzle games attract the game player a long time. Story is an important element of adventure games, as well as in RPG and ARPG. If the story is not exciting, the game player feels that the game is a dull game. The story is the essential point of attractiveness in many games. The attractiveness of game relates strongly with the story. Competition is very popular style adopted by many games. Two or more players can play in the competitive game in traditional games without computers. On the other hand, video game simulates some necessary players for game progress. Therefore the game player can play a competitive game alone. However, the attractiveness of competition is not in playing game alone but in fighting with other players in the game. Sound and graphics are the representative features of video games by using multimedia techniques. They are also extracted as the elements of attractiveness from all game categories. This fact suggests that sound and graphic are general attractiveness elements of video game. The game player feels attractiveness from beautiful sounds and colorful graphics.

4 Which technique realizes attractiveness ?

For embedding the game's attractiveness into an educational system, we have classified the game's attractiveness into three groups, based on the needed technique; multimedia techniques, standard engineering techniques and other techniques out of engineering. In this classification, the standard engineering techniques do not include the multimedia techniques. This classification indicates the limitation of attractiveness realized by standard engineering techniques.

The multimedia techniques realize sounds, graphics and so on as the game's attractiveness. However, we cannot find important issues for educational technology focusing on multimedia techniques themselves, because it is obvious that high multimedia techniques provide high quality of sounds and graphics. In addition, creating good multimedia materials and products is also out range of engineering technique so that we cannot well-handle this issue in educational technology. As for our handling area, we think that it is an important issue to determine how to control and integrate educational multimedia products in order to assist learning. The standard engineering techniques realize some attractiveness; time restriction, stage clearing, level up, puzzle, competition and so on, and therefore it is available to embed them in CAI systems. However, our investigation on embedding attractiveness is not enough because we cannot generally indicate how to embed attractiveness appropriately into arbitrary tasks and aims. This issue is very important for designing and implementing attractive educational systems Some of the attractiveness elements such as story, sounds and music are out from the engineering techniques. For example, a good story can be created by a professional writer and comfortable sound and music are composed by a professional composer. They are not generally engineers and they do not use engineering techniques for their creations. Therefore, we do not positively handle these elements of attractiveness on the engineering level.

5 Conclusion

In this paper, we have described the classification of video games and extracting attractiveness from video games as the basic investigation for developing attractive computer software. We also indicated the range for well-handling game's attractiveness based on engineering techniques. We believe this range is effective guideline for design and implementation of attractive educational system.

Implications for Virtual Reality in Natural Resource Recreation Management Curricula

Jeff Hill, Bob Buerger, and Jim Herstine
Dept. of Health, Physical Education, and Recreation
University of North Carolina at Wilmington, USA
hillj@uncwil.edu

Abstract: Since 1992, researchers at the University of North Carolina at Wilmington have been gathering data in multiple media formats concerning physical impacts due to recreation on Masonboro Island, a pristine barrier island off the coast of Wilmington, North Carolina, USA. The data have been integrated into a hypermedia database and are now being used by both managers of the island, as well as researchers. More recently, the hypermedia database was also used by students in a Coastal Natural Resources Recreation Management course in developing coastal management plans. One primary limitation which emerged from utilization of the hypermedia database in both academic and professional settings was the static media itself (eg. photographs, drawings). To address this limitation, navigable virtual reality images of Masonboro have been integrated into the hypermedia database utilizing Apple Computer's QuickTime VR system.

Introduction

Wilmington, located in coastal southeastern North Carolina, USA, is blessed with an abundance of natural resources. Perhaps the most notable of these is Masonboro Island, an 8 mile long, 5000 acre pristine barrier island ecosystem. Unlike the adjacent barrier islands, Masonboro remains undeveloped and primitive. For this reason, the island is managed by the National Estuarine Research Reserve as a critical site for not only protection of the resource, but also education, research, and traditional uses, such as fishing, oystering, and camping. The proximity of Masonboro Island to Wilmington, and the relative ease of access, allows high levels of recreation, and the resultant environmental impacts, to occur. Despite these pressures, the extremely dynamic nature of the barrier island ecosystem provides significant remedial forces within a geologically short timeframe.

The Hypermedia System

Since 1992, researchers at the University of North Carolina at Wilmington have been studying this relationship between environmental impacts due to recreation on Masonboro and the forces which mitigate this impact. Through funding from both the North Carolina National Estuarine Research Reserve and the North Carolina Sea Grant Program, an interactive, hypermedia-based computer system has been developed which encompasses the longitudinal data which was gathered on Masonboro Island. The focus of the system is to allow managers of the island to inventory, monitor, and assess impact data on-site. To this end, the system has been developed to be powerful, easy to use, and portable.

In addition to this managerial application, a collateral use of the system has emerged and has been implemented into the university curriculum. In the fall of 1994, the Masonboro Island hypermedia system was integrated into the REC366 Coastal Recreation Resources Management course at the University of North Carolina at Wilmington [Hill & Buerger 1996]. Within this course, the case study method of education as devised by Christopher Langdell [in Edginton & Griffin 1983] has been implemented allowing the students to use the hypermedia system to develop a management plan for Masonboro Island which accommodates traditional recreational uses, while at the same time protects the coastal resource base. To complement the use of the hypermedia system, the students, working in management teams, perform on-site analysis and interpretation, and work directly with professional resource managers, as well as additional mentoring resources, in order to fully realize the advantages of case study methodology [Willings 1968].

Through the use of the hypermedia system and this experiential implementation of case study method, the students literally assume the role of the administrator of the reserve in developing a management plan for the island. In essence, the hypermedia system allows the students the opportunity to effectively and easily access longitudinal impact data which was generated by university researchers and is currently utilized by reserve resource managers. Consistent with case study methodology, the system provides the students with powerful tools for accessing, organizing, manipulating, and analyzing this data in a manner which accommodates individualized styles of learning [Zeigler 1982].

This hypermedia system has proven to be an invaluable tool in the professional preparation process at the University of North Carolina at Wilmington. Understanding and interpreting real-world data, and applying it to management of natural resources is a vital educational experience for future resource managers. However, as with any system, there is room for improvement. A primary limitation of the existing hypermedia system is that it constrains the students' perspective in analyzing and interpreting the photographic hypermedia data in the system to that held by the original researcher. This constraint surfaces in two ways. First, when analyzing a photographic record of an impact site, the student only sees a static image of the site. He or she is unable to see, know, or understand the context within which the photographic record was taken. Second, the point of view from which this static photograph was taken was chosen by the researcher, and not the student. If given the opportunity, the student may have chosen an entirely different perspective from which to record the photographic representation of the impact site. This individualized perspective of the impact site could greatly enhance the learning potential of the system and alter the students' analysis and interpretation of the site itself.

Integration of Virtual Environments

To address these limitations, researchers at the University of North Carolina at Wilmington have integrated virtual reality (VR) environments of Masonboro Island into the hypermedia system. VR offers several potential advantages within the educational realm. First, consistent with case study methodology, VR allows learners to "more directly enter those digital worlds that, until now, we could only passively observe through the window of the computer screen" [Porter 1992, p. 42]. Second, this more direct interactivity should "amplify the powers of the mind to see previously hidden relationships in complex sets of data and to absorb, manipulate and interpret information more quickly and completely" [Virtual reality 1992]. These potential advantages of VR directly address the limitations of the existing hypermedia system, and provides educational flexibility by empowering the learner [Pantelidis 1993].

The virtual reality system selected for integration was Apple Computer's QuickTime VR. In QuickTime VR virtual environments, the user can freely navigate a "3 dimensional" world within one's computer. It is possible to develop these worlds to the extent where the user can gain a 360 degree perspective of the site, "grasp" objects within them, "pick them up," and "examine" them. It is important to understand that this is not "immersive" virtual reality wherein the user interacts with the virtual environment through such devices as headsets and datagloves. Instead, QuickTime VR allows the user to examine photographic panoramas or objects within a window on the screen using the mouse and/or keyboard to direct navigation and perspective. This allows for tremendous educational flexibility within the system while minimizing hardware requirements and costs.

The integration of QuickTime VR virtual environments has greatly extended the functionality of the Masonboro Island Hypermedia System and enhanced its potential as an educational tool. Therefore, it is our intent to incorporate the VR system into the undergraduate professional preparation curriculum in Natural Resource Recreation Management at the University of North Carolina at Wilmington. In using the VR system to develop management plans for Masonboro Island, the students will have the ability to adjust the perspectives of the photographic images through navigation of the scenes. This will allow them to understand the context within which the environmental impact occurs and to pick their own perspective from which to analyze and interpret the site. QuickTime VR virtual environments have the capability to expand the use of case study method and to improve student integration into the overall learning environment.

In Search of Integrated Education: A Knowledge Management Approach to the Design and Development of Computer-Based Patient Education and Awareness.

S J Hill, N J Fiddian, W A Gray. University of Wales College Cardiff, Computer Science
Department, Cardiff, South Wales, UK.
D Morrey. Velindre NHS Trust, Whitchurch, Cardiff, South Wales, UK

Abstract:
The provision of networked information resources and associated software applications has fostered important implications for the development of computer-based patient education and the way in which it can be placed and utilised in the healthcare setting. In the field of medical informatics, there is a recurring theme of integration and information sharing. At Velindre Hospital (a specialist cancer treatment centre) in Cardiff, South Wales we have developed *patient-knowledge management* software which embraces networked resource, networked computer-based education and the facilities for trading 'information and knowledge commodities', relating to patients, across information system boundaries. The *patient-knowledge management* software required to develop and support patient education in this setting is called DEICOMAH.

Introduction

In many cases, the competencies of information technology in the provision of computer-based education have out-paced the theories behind the paradigms needed to implement specialised educational applications. This is particularly true of computer-based patient education in clinical environments. Here, patient education is often inextricably associated with meaningful patient consent to treatment, shared decision making, patient compliance to treatment, and the triggers required for patient behavioural change [Skinner 1993, Gillispie 1993]. We believe that educational software for patients' informational and awareness requirements can not be developed in isolation from the information-rich environment in which they reside. As an example, computer-based patient education can now be utilised to contribute to external healthcare issues and objectives such as clinical effectiveness, needs assessment and patient-centred decision making. In the development process, consideration must be made as to the nature of these external requirements; development strategies must evolve to address the information flow between patient information systems and the boundaries of patient educational software. For these reasons, we have recontextualised the authoring process by encapsulating it in DEICOMAH - our patient-knowledge management software. We believe the supportive concept of knowledge management is necessary to develop educational applications *which recognise the potential of patients as health care resources who can provide unique insights into their own preferences for treatment and care* [Casper 1994]. This requires a well managed, computer-based, educational environment which can:- provide computer-based education and awareness strategies for patients, elicit patient-feedback and commentary about important health care issues (which we term a *patient knowledge response*), and store this within the patient information system in a format which health care providers can utilise. We refer to the concept of computer-based educational software which provides an information link between institutional mission objectives, issues and requirements, and localised educational support, as *educational integration*.

DEICOMAH and Patient-Knowledge Management

Expanding upon Knowledge Management Definitions

Knowledge Management in a medical context has been informally defined as the authoring, management, selective retrieval and annotation of knowledge for such purposes as education, problem solving and decision making [Greenes 1991]. However, this view of knowledge management does not fully embrace the characteristics and requirements of educational software for patients. With reference to the above, we have extended this existing concept and offer a description of patient-knowledge management which addresses the increasingly active and participatory role of patients in their own health care and their potential as a health care resource. In *Patient Knowledge Management*, we include: the authoring of computer-based patient education, the management, retrieval, utilisation, annotation and documentation of clinical educational resource, the mechanisms necessary to elicit feedback and commentary from the patients as they become more aware and knowledgeable about their disease, treatment options, side effects and outcomes (patient knowledge response), the storage of patient knowledge responses in the patient information system, and the use of the patient information system to provide patient data in educational applications..

An Overview of DEICOMAH

The DEICOMAH knowledge management software comprises a set of extended authoring and management tools necessary to attain the requirements of educationally integrated and well managed software in a computer-based educational environment [Hill 1997] . The 'electronic book' metaphor, which has been well documented in the field of educational computing and addressed in the field of education in medical informatics [Barker 1991, Richards 1991, Collis 1991, Santer 1994, Mooney 1995], is used to promote user-centred, collaborative development. DEICOMAH can be used to switch between three modes of development and management. Central to the knowledge management philosophy of computer-based patient education developed under DEICOMAH, is the provision of facilities to browse, identify, utilise and define external patient-related data which can be contributed to or incorporated into the educational software. Facilities are provided in a similar vein with additional administrative tools to utilise, develop and manage re-usable clinical educational resource. Administrative facilities also ensure data integrity amongst educational applications sharing both secure patient clinical data and educational resource. Once identified, the knowledge management facilities of DEICOMAH administer the necessary procedures to incorporate this into the application design. Other interfaces are available for defining new clinical or educational relational data structures if they are not identifiable in the patient information system. Educational resource browsal tools are also available for viewing and utilising multimedia such as images, text, audio and video files. Management facilities further include query tools, methods to match educational and clinical resource to individual electronic books, chapters and pages. They span: automated documentation and report generation, interactive views of the educational environment in which the educational software is used, data table definitions and data update/deletion facilities, a 'spy hole' facility to view run-time versions of individual pages in other applications, and access to the external patient information system data dictionary.

Work in Progress and Conclusions

At Velindre Hospital, we have been using DEICOMAH and the knowledge management paradigm to develop computer-based patient education, and have examined extending our philosophy to incorporate staff awareness applications into the educational environment. ADV (ADVisor) is computer-based educational software for male cancer patients addressing bladder, testicular and prostate cancers. It also addresses aspects of male sexuality often affected by the resultant treatment. The application is not used directly by patients, but supports the provision of tailored information for patients during cancer counselling and advice sessions with a specialist cancer nurse. Video, sound, pictures and text are presented to the patient and during the awareness process, information is elicited from the patient regarding preferences, concerns, expectations and decisions. This knowledge response is then stored as a supplement to the Hospital's patient information system. We are currently working on new interfaces of the patient information system to provide clinicians, responsible for the patient, with this unique patient response to health care issues, presented alongside standard medical records. We hope to extend the use of ADV to support informed consent to treatment and incorporate more formal methods of decision analysis if required. A full evaluation of knowledge management and its supportive concepts will shortly take place and early indications suggest that our knowledge management philosophy and supportive conceptual development paradigm have been of particular benefit in allowing nurses, clinicians and informaticians to conceptualise educationally integrated applications, and additional concepts such as databases, entities, attributes, entity relationships, modules, information systems, access control and security.

A Multimedia System for Reinforcing Computer Programming Skills

Peter S. Ho Geoff Whale
School of Computer Science and Engineering
University of New South Wales, Australia

E-mail: peterh@serg.cse.unsw.edu.au
geoffw@cse.unsw.edu.au

Abstract: Computer programming is a discipline that requires the acquisition and application of a wide range of knowledge. Students who find the techniques and skills difficult to learn are often not well served by remedial classes. This paper describes a system, *Periscope*, for reinforcing concepts in programming by providing an experimental environment in an instructional multimedia framework. Instructional material contains embedded examples that can be executed and can also be modified by the student in controlled ways. Periscope incorporates several forms of assessment that can be used both to identify students in need of help, and to measure improvements in learning resulting from the use of the system. It is platform-independent, and supports examples expressed in current imperative implementation languages.

1 Introduction

Learning to write computer programs is often difficult for students. For many, this may be the first time they have had to do something that is significantly more complicated than installing and using standard software packages. A majority of our first year computer science intake may be classified as novices, who are often overwhelmed by the technology, the language and the theory.

As a consequence, roughly 20–30% of the class will find it difficult (if not impossible) to keep up with the programming material—this roughly equates to a 10–15% overall failure rate, which is clearly undesirable. In addition, others may simply struggle through the course with a fragmented knowledge of the syllabus, which will handicap the student in their later years.

Over the next three years, first year failure rates are expected to increase as a direct result of lower tertiary entrance requirements. This is brought about by a desire to maintain student numbers at an economically viable level in the face of a decline in interest in some computing courses.

Computer programming is a complex task, requiring multiple skills and levels of understanding (see, for example, [Volet & Lund, 1994] and [Pea & Kurland, 1987]). Students naturally learn skills at differing rates, presenting increasing problems for instructors. The currently accepted practice of lectures supported by tutorials does not adequately cater for students who are struggling to keep up with the programming syllabus. Struggling students are less active, more withdrawn in tutorials and tend not to ask questions as the more advanced students dominate and set the learning pace. Suggestions that slower students be segregated from smarter ones is not a philosophically acceptable solution.

Recent attempts to conduct remedial tutorial classes on a voluntary-attendance basis was met with only moderate success. It would appear that students often do not want to be publically identified as those needing remedial work and often do not attend such classes. In addition, it was found that by the time we could identify the weaker students, these students often felt demoralised and were difficult to motivate.

2 Technological Support for Remediation

We need some form of remedial or reinforcement support that operates on a one-to-one basis. Committing additional teaching resources to remedial support is not always practical for anything greater than a small number of students without its becoming a time and monetary drain. Under these circumstances, we need to consider the use of multimedia computers as an adjunct to traditional teaching methods. Such a system would:

- be untiringly attentive, allowing the student to progress or repeat the teaching material at his/her pace;
- retain a student's right to anonymity in the class with respect to his/her performance;
- be used to monitor the students' level of competency and progression in order to provide instructors with data on which students require personalised help;
- allow a student to explore and experiment with code structures in a protected environment that serves to reinforce concepts introduced in lectures; and
- be flexible enough to present to a student materials that demonstrate the techniques that lead to a particular design or problem solution as well as the designs themselves. This is consistent with current metacognitive approaches to learning [Volet & Lund, 1994].

Such a system is under development. Through the use of multimedia incorporating color, animation, program simulations and interaction, the system is perceptually varied, easier and more interesting to use than similar print based materials. Being self-paced and less threatening than a classroom full of students, it is likely to be more effective. Although designed to help weaker students, advanced students may also use the system to reinforce and test their programming skills.

3 The Periscope System

A system for remedial or reflective learning of computer programming should be flexible, easy to use, and platform-independent. It should show the processes that lead to a particular design as well as the design itself, and it should incorporate several kinds of assessment. The software described in this paper is called *Periscope*, which (roughly) stands for Personal Environment for Reinforcing Skills in Computer Programming.

Figure 1 shows Periscope's components, which are based on standard multimedia technology. It uses a browser to present brief instructional material consisting of hyperlinked topics that introduce aspects of programming and software design, and are illustrated with many concise examples. The instructor develops the material with the help of the script editor; the student later views it using the browser.

BEST COPY AVAILABLE

The key to the system from the student's view is the set of programming examples. These examples are not only illustrations of the processes and concepts being explained, they are also active regions, which when selected open up the control panel for a complete experimental environment. The control panel allows the student to invoke three main functions:

Run – creates a simulation environment where the currently selected program fragment is able to be executed. The simulation shows multiple views of the execution process, in order to enhance the student's understanding of program execution. As well as an activation record stack and the current textual execution point, such as is found in many debuggers, the simulation includes an abstract view of the data, modeled on the *Druids* data structure animation system [Whale, 1996]. Execution may be single-stepped or may proceed at a user-selectable rate.

Edit – opens an editor in which parts of the program fragment may be modified, thus giving the student an opportunity to observe changes in algorithm behavior. Only portions identified by the instructor as suitable for experimentation are editable; this reduces risk that the student may produce gibberish. After editing is complete the program is recompiled, and if syntactically and semantically acceptable it becomes the current program for animation.

Test – starts a sequence of assessment tasks associated with the example. Assessments range from simple multiple-choice questions to an analysis of the example as modified by the student according to the specifications given in the instructional material. The visual testing environment complements the experimental setup, as recommended by Szabo [Szabo et al, 1981]. An interesting feature is the use of Jody Paul's confidence-measuring response triangle [Paul, 1994], a mechanism that records a student's confidence in their answers on a three-choice scheme, and thus rewards partial knowledge.

An important component of the system is the script editor that permits the instructor to devise the whole course of instruction. As well as assisting with hyperlinks, it allows examples to be properly constructed and tested, with editable regions and parameters identified. It also supports setting appropriate assessment tasks. Assessments is an important aspect of learning, unless devising tests is made easy, benefits to the students will not be realized.

4 How the system is used

Periscope provides a rich set of functions that enables instructors to build elaborate hyperlinked and animated instructional scripts that can be viewed using a browser. These scripts determine the behavior of the browser when it is used by the student. For example, a script that is designed for remediation might contain more algorithmic animations and opportunities to experiment with example code fragments than one that is designed to reinforce learning.

Two of the key features in Periscope are its ability to animate difficult to understand algorithms and to provide a controlled environment in which students can dynamically explore and alter parts of the code using a program editor. The ability to alter the code exploits the benefits of exploratory learning as students are allowed to observe what effects their changes have on the code and serves to answer "what if" questions.

Periscope may also be scripted to identify conceptual gaps and difficulties that students may have with the syllabus. The range of tests include fairly simple self assessment tests through to elaborate assessments that require students to develop solutions based on their deeper understanding of the material rather than the regurgitation of facts.

It is essential that the instructor employs sound instructional design principles and is conscious of the medium's limitations when preparing the scripts. For example, reading large portions of text is a strain when viewed on a (small or slow refreshing) computer screen. Likewise, the placement, choice and quantity of examples used are equally important in helping to focus the student's understanding. The success and effectiveness of Periscope rests squarely on the quality and the design of the scripts.

5 Implementation

Periscope has only been partially implemented at the time of writing. The major components are implemented as Java applets to increase platform independence. The browser is either Netscape Navigator (version 3.0 or better) or

HotJava (the former applies more restrictions to locally-run applets than is warranted, but is more widely accepted for WWW browsing).

Data is passed between components of the system primarily as HTML scripts, with additional tag types used to specify parameters and attributes. In order to speed access to examples, some precompilation of the example code fragments in the script occurs at the time the instructor devises them. The control panel avoids compiling an example into Java classes for the simulator unless the student is working on a modified copy. Both the compiler and the simulator are browser plug-ins.

The current implementation of Periscope only supports (in the script) example code fragments that is either C or Java. C represents the most common choice for the imperative language in first and second year programming courses at present; Java is likely to become more widely adopted over the next few years. In principle, any procedural language that can be modeled in Java could be used for executable examples. All that is required is a browser plug-in compiler module for the chosen language (itself a major design feat, however).

Development is being carried out in a Unix environment presently. We recognise that it is important that Periscope be available for PCs and Macintosh platforms and the methodology used is intended to achieve this aim.

6 Evaluation

Whether Periscope will be a useful adjunct to computer science teaching will depend on empirical studies that are being planned. At minimum, its assessment scheme, used with a rigorously designed screening test, can identify students who are not thriving early in the semester. These students can be randomly assigned to three treatment groups: those using Periscope for remedial work, those attending additional face-to-face remedial classes, and those attending only normal classes for the remainder of the course.

What are the prospects for being able to establish improved learning among these students? A study [Whale, 1997] that involved only an animation system without integrated instruction showed that such tools may be more effective when used for revision than for new material. It is anticipated that the provision of instruction and a more flexible experimental setup can only increase its usefulness.

A Distance Learning System for Computing and Information Systems Students

Dr. Peter Holt Chair,
CCISM
Athabasca University
Box 10,000
Athabasca, AB, Canada
T9S 1A0
holt@cs.athabascau.ca
http://ccism.pc.athabascau.ca

Abstract: The design of a multimedia distance education learning system is more than creating a collection of multimedia courses. First we identified the learners and designed a learning model based on their needs and curriculum requirements. With systems development concepts such as rapid prototyping, object oriented design, and participatory we developed an integrated environment of courseware, instructional systems, and administrative systems to support the student from admission to completion of the programme. With our approach the roles of researcher, developer, learner, and teacher become more overlapped.

Design, Development, Delivery, and Evaluation

The goal of Athabasca University (AU) is to provide lifelong open learning (Race, 1994) by reducing barriers to education. Coordinators create courses at the University site while tutors are distributed across Alberta and students are distributed across Canada. Courses have been primarily print-based with telephone access to tutors. However, AU has been planning an online learning system since 1985 and has made progress towards that goal in several areas. Our goal in the Centre for Computing, Information Systems, and Mathematics (CCISM) is an electronic body of instructional support tools, curriculum content, and design strategies from which we can select materials for a particular course or module.

The first consideration in designing any learning system should be the learners. A system designed for mature self-motivated adults may be quite different from one for junior high school students. Students of CCISM are mature, self-motivated and open to using technology-based learning. The concepts of guided self-discovery learning (Holt, Fontaine, Gismondi, and Ramsden, 1995) and apprenticeship learning (Collins, Brown, and Newman, 1990) provided a framework for us in CCISM for developing an open learning system for a motivated adult learner. Within that framework, collaborative learning (Harasim, 1993) is particularly important for students in a CIS curriculum (Baecker, 1991). Finally, government, private industry, and students are pressing for an applied orientation in CIS that sometime conflict academic orientations. Situated learning - learning in real life situations (Brown, Collins, and Duguid, 1989) helps bridge academic motivations and the need for applied education and to support reflective and experiential learning (Norman and Spohrer, 1996). In summary the objectives of our learning system are to: 1. have the student learn at the time and place of their convenience,2. support self-guided discovery and apprenticeship models of learning, 3. support collaborative learning, 4. support situated learning, and 5. support both reflective and experiential thought.

We believe our objectives are best met by World Wide Web (WWW) based technology. We expect WWW standards for learning systems design will evolve in the same manner as standards for networking layers. To support guided self-discovery, we provide learning materials in hypermedia format (HTML) with links to WWW-based learning materials (Holt, Fontaine, Gismondi, and Ramsden, 1995) along with tutorial guidance. Collaborative and team building is supported by computer mediated communications (Holt and Gismondi, 1995) We extend the guided self-discovery concept to a apprentice model by project courses and work-experience. Students in projects courses and in work experience roles use tools for collaborative learning in helping design and implement the distance learning system environment (Holt and Gismondi, 1996. Computer based communications, projects, systems development work, and manning a "virtual help-desk" support situated learning The virtual helpdesk will be extended in the near future allow course specific help amongst students (Bishop, Greer, Cooke, 1996).

Experiential thought is easily integrated into computer based learning systems. Students are continually interacting with the computer and with one another through the computer. But reflective thought is more difficult concept to tie directly to the computer based learning system. Reflective thought in a CIS curriculum occurs in analysis and design and generating of algorithms. It may be nurtured by interaction with students and tutors and by access to appropriate computer based tools. A major role for AI in supporting reflective thought may be to support in a general way student exploration and collaboration (Clancey, 1993).

Participatory design in which users are directly involved in computer systems design has more recently been extended to the concept of learner centered design learning systems. (Norman et al, 1996). Learning occurs through the process of interaction with other learners and the environment. We extended Norman's (1996) concept of learner centered design by involving students in creating the courses and the learning environment itself. Students working on course conversions, design, and development have enhanced both the process and the product.

As in any development effort we are concerned with re-usability of code and integrity of data. Thus we try to use principles of oriented analysis and design such as data encapsulation and inheritance. Examples of how we follow the principles include things such as: data encapsulation - we keep the map coordinate files separate from the HTML and we will keep all the external link references in separate global link tables; and inheritance - we develop templates that can be modified for specific uses. In the longer run we hope the market will provide tools for building inheritance hierarchies for page objects and our authors will simply point and click and modify the objects. Currently shortcomings in current WEB technology constrain this approach; we have not found that development tools have matured to stage where we are comfortable abandoning "manual" HTML coding.

Rapid development of course materials is critical for the CIS curriculum. Student workers use the WWW available public domain visuals, HTML, and shareware utilities such as search engines and online testing systems to develop rapid prototypes. These materials are critiqued and revised by educational technology professionals. They iteratively replace the prototype material with more sophisticated material. Then we use those standards and course HTML templates developed in-house to quickly prototype new courses. Experience with the course design and delivery lead to modifications in the course that evolve the templates in a cyclical process

Other pragmatic approaches we have derived from systems design wisdom are naming conventions for files, and the creation of global directories for shared materials shared amongst courses (similar to the library concept). We also are looking at a source maintenance system (e.g UNIX based RCS for our students doing HTML from a distance) to handle file sharing by team members. We will be assessing special servers such as Hyper-G (Andrews, Kappe, Maurer, and Schmaranz., 1995).

Implementation of our learning system has been supported by an institutional wide instructional tracking system containing students identifiers, names, grades, course progress etc. It shares a database with the registration system maintaining data integrity across the institution. This reduces errors and frees up the need for redundant data entry time. Administrative systems support includes

Web-based registration and payment, and the integrated information system for registry, course materials, and finance. One of the most important areas that will require inter-institutional cooperation is a distributed library system.

"Situated research" is a very important concept for us. We believe the WEB is supporting a new research paradigm. Currently, much research in educational conducted in laboratories with statistically significant results and discussion those results being published two to three years after the fact. The WEB provides a means for other researchers to immediately experience students educational experience as the student does (visit http://ccism.pc.athabascau.ca). Further, the students become a direct part of the research and development cycle. Finally, we can pursue "situated research" in learning systems design and areas such as student modelling (Holt, Dubs, Jones, and Greer, 1994).

Synchronized Audio/Visual Web Tutorial Modules

Dave Hurley
Sr. Computer Specialist
Biology Program
University of Washington
Box 355320
Seattle, WA 98195-5320 USA
dhurl@u.washington.edu

Abstract: A relatively recent development in Web-based technology has provided the means to disseminate audio files simultaneously with graphics and text. This technology is better suited to the current limitations of bandwidth and speed of Internet connections than video, generates relatively small files, and can be augmented with vector-based animations as well as static images or text. The process for creating the audio files and the list of images to be synchronized is not difficult and requires software that is freely distributed. We are using this technology to create tutorial modules for problematic concepts in a majors' survey course in Biology.

In those university level courses where the instructor does not rely on a textbook, lectures are the primary source of information for the course. Students are required to be present in a specific location at a specific time, and, unless the lectures are videotaped, there are no further opportunities to hear and see the same presentation again. This limits accessibility to the course material and it does not allow students to review the information exactly as it was presented: they have only their notes to rely on, and these are not always completely accurate. The instructor may hold office hours where students can ask questions, but this is often too intimidating a setting for the student, or time conflicts prevent such access. One method of augmenting the live presentation of lectures is to videotape them and make the tapes available to students at a facility on campus. Videotaped lectures are often useful for many students, particularly those with language difficulties or processing disorders such as dyslexia, as they have control over the speed with which the tape progresses. The linear nature of videotape, however, prevents easy navigation between noncontiguous segments. In addition, the videotapes cannot be duplicated rapidly or cheaply enough for distribution to large lecture classes. Ideally, students should be able to review information germane to their courses, with fewer restrictions on access, but the material would be as immediate and as accurate as lectures. A relatively new Web-based technology may make such review possible.

This new technology, called Real Audio Synchronized Multimedia, allows a World Wide Web browser to play audio files that are synchronized with web pages. At specific times during the playing of the audio file, the page being viewed in the browser changes. This is not controlled by the user, but by a list of linked web pages created by the content author and interpreted by the audio player. Since the audio files begin playing a few seconds after they begin downloading, the user need not wait long periods of time for the entire file to download before listening to it. This also means that the audio file can be quite long – a one hour lecture typically begins playing 5-10 seconds after the request to the audio server has been made. This is true regardless of the speed of the user's connection: a 14.4 modem connection behaves about the same as an Ethernet connection, although the sound quality is somewhat reduced. There are a set of VCR-like set of controls visible that allow the user to pause, stop, jump forward or back in the file. The correct page is then displayed according to which part of the audio the user has selected.

The technology for producing and distributing streaming audio files synchronized to web pages has many advantages over streaming video or other web-based content delivery schemes. File sizes, and therefore storage requirements by the server, are approximately 3600 times smaller for these audio files than for video files: 3.8 Mb per hour for encoded audio files versus 3-5/Mb per *second* for video files. An entire year's worth of lectures could be stored on a 1 Gb removable cartridge for about US$90. The cost to the student is nonexistent as the client software is a freely distributed web browser plugin or standalone player. The software needed to record and encode such audio files is currently available free, while the server software is relatively inexpensive, especially when compared to video serving software. Once the audio files have been recorded, an encoder compresses them sufficiently that a one hour lecture file is only 3.8 Mb in size. The encoding process takes approximately one-fifth the length of the audio file, but does not require an operator's presence once encoding has begun. To synchronize Web pages with the audio file, any text editor may be used to create what is essentially a list of start and stop times for specific URLs. This text file is then encoded into a binary file that is placed on the same server as the encoded audio file.

The time required to assemble the audio and visual components of a synchronized set of documents depends on whether the content will be created *de novo* or taken from videotapes. If created from scratch, a written script greatly facilitates recording of the audio segment. On the other hand, digitizing the soundtrack of a videotape can be done in real time, although we have found that some editing is necessary to remove undesired segments or to add silent sections at the points where a new web page is loaded. Graphics creation or scanning is performed as it would be for any web page. Once the audio files are created and web pages are created that are linked to the desired graphics, the audio file can be encoded and the synchronization list can be created in a text editor or word processor. Start and stop times are listed for each web page in a return-delimited list and saved as a text file. This file is then encoded into a binary file and placed on the same server as the audio file. All other files may reside on any web server, anywhere. Files can also be set to be served locally from a hard disk or even a CD. Vector-based animation files can also be linked in the same way as graphics files using Macromedia's Shockwave Flash program for content creation and plugin for viewing. These files are small enough that downloading and playing them does not significantly degrade sound quality, although there are fewer operating systems (only Windows 95 and Macintosh System 7.5.x and Open Transport 1.1 or higher) that can take advantage of this feature than for static images.

We are beginning to evaluate this technology for delivering course content to students over the Web. Our educational goal is to provide a means for students to review and reinforce concepts presented in lectures, but without the restrictions of either live lectures or videotapes. By providing a means of studying that is independent of location and allows for non-linear jumps between segments of a presentation, the accessibility to the teacher's thoughts should be greater than that provided by lectures, office hours, or videotapes.

The initial stage of evaluating such methods will be the development of discrete modules centered around those concepts that are typically the most difficult for students, and hence require the greatest amount of time to assimilate. Should these methods prove to be effective, they could then be extended to include materials from all lectures. This form of content distribution could then, conceivably, be used in place of lecture, thus freeing the instructor and students to devote their time together to discussion of the material, rather than merely participating in a one-way transmission of information.

We hope to evaluate the effectiveness of this method by giving students a pretest and post-test on the material covered. Test scores will be analyzed for statistical significance.

Experimental Collaborative Information Networks

David Ibsen, International Centre, University of Alberta, Canada, Email: David.Ibsen@UAlberta.ca

Abstract: Collaborative Information Networks (CINs) are based on the principle that the collaborative monitoring, indexing and disseminating of information is more efficient than individual searching and monitoring. Following a brief introduction to CIN concepts and structure the following experimental networks are introduced: international news networks, networks for leaders, and an educational technology network.

Introduction:

The author has been conducting research related to Collaborative Information Networks (CINs, pronounced "Kins") since 1985 [Ibsen 1995]. The following excerpt from that paper summarizes the basic rationale for CINs:

> "It is proposed that the collaborative monitoring, indexing and disseminating of information is more efficient than the current practise of individual monitoring. Individuals in a collaborative network would monitor and index a limited number of information sources and share the results with others in the network. This would allow the collective monitoring of more sources of information than is possible by individual monitoring."

In the above mentioned paper, the author proposed developing CINs based on his proposal for an information structure (network and topics proposed by the author) and seeking people to collaborate in developing a network. In this paper the author is describing and proposing experimental networks based on information needs, existing communication networks and trigger goals [Ibsen & Lewis 1993]. Prior to a discussion of experimental networks a brief overview of the experimental network structure in given.

Experimental CIN Structure:

The basic structure of experimental networks is small groups of people sharing information using email with reference to sources of information such as Internet URL's (Uniform Resource Locators) and published materials. Groups are organized according to topics and the following levels of participation. Level one participants passively receive information which has been indexed by level three participants. Level two actively share information on specific topics with level three participants. Level three participants monitor at least one source of information and collaboratively share information with each other. They collectively select and index information to be shared with level one and two participants on topics of common interest. It is anticipated that no more than ten people work together at this level. Once that number is reached the group could subdivide by subtopic or other interest.

Funding for experimental networks (an email address and time) can easily be provided by network participants. In prototype networks funding could come from charging fees to level one participants. Another possible source of funding is to seek funding from commercial advertising.

To gather data and ideas for prototype networks the author is proposing to establish an experimental CIN related to CIN development with at least two sub groupings: one on people aspects of the network (the author could facilitate this) and the other on technical aspects of the network (the author is looking for a research partner(s) in this area). Other experimental networks are described below.

Experimental Networks:

As of March 10th, two sources of information are being used to facilitate the following networks: an international news network, networks for leaders, and an educational technology network. Two other networks (one on special education and the other for a non-credit class of adult learners) were explored but interest in participating in these networks was limited.

The international news network has several sub networks related to the author's interests and contacts which have similar interests. The sources of information for these networks are: Mercury Mail's <http://www.merc.com> free email news service funded by advertising and the UAISN (University of Alberta International Students Network) list server sponsored by the International Centre at the university. "International Update" another email list service of the university is also sent out to UAISN subscribers. The author selects information from these two sources and sends it to others participating in information networks which are of specific interest to them. These networks include the leaders networks mentioned below.

An email network for leaders has been developed from the need for one of the key organizations in the network to communicate with other organizations in the network re: special functions which are of potential interest to all organizations in the network. The initial thrust of the network was advertising a seminar sponsored by this organization. Information had been sent out by post inviting leaders to a breakfast meeting with an internationally known seminar speaker. The author was hired to phone these leaders to remind them of the breakfast and to gather email addresses and fax numbers for future communication purposes. It was found that a few organizations had email and most had fax. An experimental email network has been set up and an email/fax network was discussed. Another group of leaders is being approached with respect to setting up a network for them. Educational leaders are also being contacted with respect to networks for them.

A network on educational technology has been established with the anticipation that this will grow into a broader network on "Career and Technology Studies" (CTSnet). This network has the most potential of all the networks being explored because most of the infrastructure is in place to develop a fully functional prototype with a significant number of users. The main issue is funding and a related issue of time for users to participate in the network. It is anticipated that, if funding were found for central network development, end users would find the network so useful that they would prefer using it, to using current methods of obtaining information. To get funding for CTSnet and other networks the author is looking for trigger goals [Ibsen & Lewis 1993], which would facilitate CIN development and the goals of organizations using them.

At present the author is the only level three participant, with one or two others interested in participating at this level. Other level three participants can be added once some basic procedures are established between those interested. The author is currently developing these procedures using his experience in facilitating the networks mentioned above.

The author also hopes to explore international networks within the next year and present a paper at the "International Conference on Computers in Education" to be held in Malaysia, December 1997. See "y'all") there eh! OK La! (Southern USA, Canadian and Malaysian/Singapore slang).

Quality in Distance Education[1]

Esther Javetz, Walden University, USA. E-mail: JavFam@aol.com

Problems in Distance Education

Distance education has been described both as different and identical to classroom teaching. There has been already a small body of research on distance education [Willis, 1992], where no significant difference was found between technology based and conventional face-to-face instruction.

Problems which have just been noticed in distance education seem to be shared by education in general. [Ehrmann 1995] points to the issue of students learning details but *not changing their own beliefs* as a result of distance education. [Jones et al. 1994] state that adult learners who think critically are better prepared to positively contribute to their communities and to society as a whole. Jones et al. propose a program for "inspiring educators to increase their knowledge of critical thinking in distance education". This emphasis on *critical thinking* is due to observed low performance. Much has been written on *transfer of learning* [Perkins et al., 1988], however, not in the context of distance learning per se. I have observed difficulties in the transfer of learning and applications to new situations. (See below). The problems of changing one's own belief, critical thinking and transfer of learning are issues from the kind of desired higher order learning that are problematic in all educational contexts [Riel, 1993, Hawkins, 1992].

A Distance Education Data Set

I have taught three quarters in a distance education graduate program. After examining my students' final papers, 36 projects, I found at least one of the aforementioned problems in many of the papers. The students' assignment for the final paper was to create a sequence of two lesson plans supported by a rationale from Gagne' and from constructivist theory. Additional theories were encouraged to be incorporated too.

Students final papers were evaluated for the application of Gagne's events of instruction and constructivist theories. The evaluation was YES (assignment fulfilled), PARTIAL(theory mentioned but not applied), or NO (theory not included).Results are shown in [Fig. 1] and [Fig. 2].

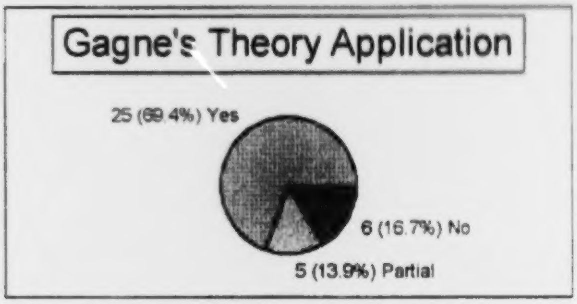

Figure 1: Success rate with the first assignment

---

[1] A fuller version of this article, including references, is available on the CD-ROM.

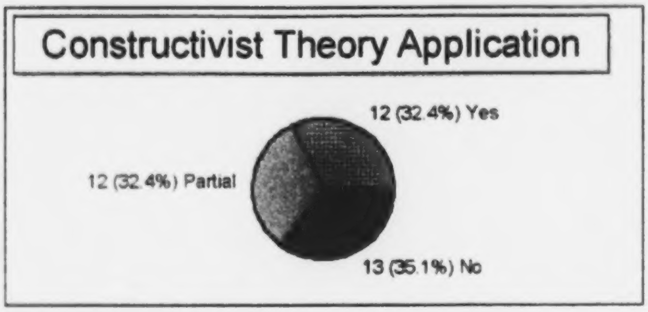

Figure 2: Success rate with the second assignment

When considering all three classes together only 69% of the students met the requirement of application of Gagne's theory, and only 32% of students met the requirement regarding the constructivist theory.

[Fig. 3] illustrates program development over time.

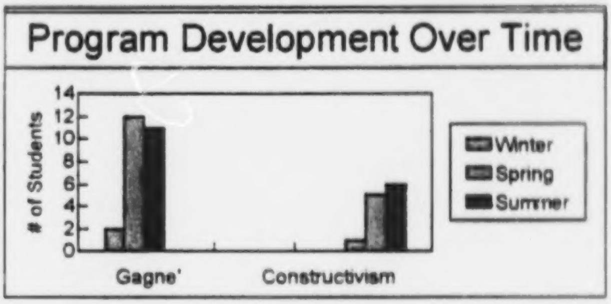

Figure 3: Increase in YES scores

In the first quarter (Winter) the number of YES evaluations is much smaller than YES evaluations in the Spring and Summer quarters. This improvement over time is true in both theories, but it is more true in the application of Gagne' theory.

Discussion

Distance learning programs need to mature. As [Fig. 3] suggest some problems will be solved over time. However, [Fig. 1] and [Fig. 2] show that a more profound change in teaching methods is required, maybe in the direction of cooperative learning, to bring upon desired quality in distance education. Cooperative learning holds the greatest promise to quality because the *multiple feedback* from group members, whole class, and instructor should lead to greater understanding and improved performance in distance education.

Problems with higher order learning have been recognized in many educational contexts. However, the solutions are somewhat different for every context. Distance education, for example, has its own set of conditions. [Turnbull 1987] already recognized five characteristics of distance education: accessible, flexible, user-friendly (with a high degree of interaction and adequate support systems), eclectic (employing a variety of media and teaching strategies) and egalitarian. Historically, these characteristics were implemented in most cases. If one listens carefully to these characteristics, one senses convenience and usefulness for the student, but not necessary curricular rigor and standards of higher order learning.

Distance Education Project in a Country with Transition Economy - Experiences and Lessons Learnt

Borka Jerman-Blazic
Laboratory for Open systems and networks
Jozef Stefan Institut and Faculty for Economy
University of Ljubljana , Jamova 39
1 000 Ljubljana, Slovenia

e.mail: jerman-blazic@e5.ijs.si

Abstract: The paper discuss the experiences gathered through introduction of distance learning at Faculty of economy at Ljubljana University. The part of the project considered with setting up of requested infrastructure is briefly presented. Future plan are explained.

1. Introduction

The tremendous changes in society over the past 25 years have broadened what is expected from higher education institutions. This has led to a change in their role and function as well as their educational structure. In addition to conventional teaching, more and more emphasis has been given to part time teaching, continuing education, retraining and different forms of vocational training, or in other words, to life long learning. The life long learning is associated very often with non-conventional teaching activities. These non-conventional teaching activities for students who work and study simultaneously mainly employ distance education methods, which can be ideally suited to these situations.

2. Country with Transition Economy

In the past decade distance teaching was established in many countries. Slovenia joint the major trend in establishing distance learning facilities relatively early, in 1994. Faculty of Economy from Ljubljana University (Ljubljana is the capital of Slovenia and the University of Ljubljana is the biggest and the oldest University in Slovenia) was the first higher level educational institution that launched the project for distance education. There are more reasons why the Faculty was the first institution to launch such a project. Later, the Faculty was appointed by the University as the co-ordination centre for all activities concerned with distance education.

The situation in country with transition economy (countries that turned their social and economic systems to open market economy after the fall of the Berlin wall) regarding the education in the field of economy changed dramatically with the changes in the social and economic life of the country. The former doctrine of socialist economy and self-management of enterprises which was common practice in all countries that appeared after the dissolution of Yugoslavia was abandoned relatively fast after the recognition of the new born states. New programs were introduced and new curricula developed. The changes in the program influenced the interest for study of economic sciences and management administration. The number of students at the Faculty of economy grow almost exponentially. From 300 new students per year, the number grow up to 1 500 (the limit of 1 500 was set up by the Ministry for education and sport) in the regular program funded from national budget sources. In parallel similar programs were launched for people that work and study simultaneously. The number of these students grow to 3 000 per year. This type of study required programs with flexible conditions, through which students are enabled to acquire degrees equivalent to those earned in regular state funded programs. This type of study where the majority of students live out from the site were the faculty is located become a challenge to the authorities and the educational staff. It becomes very clear that the technology which was introduced in the country through the academic and research networks should be used to meet the needs and the new challenge. Distance teaching appear to be the most efficient way to meet the requirements for the grow of the demands expressed in the regular and especially in the education programs for students that work and study. So, the project "Distance education at the faculty of economy" was launched and organisational structure was set up.

3. Distance Education at the Faculty of Economy, Ljubljana University

According to Keegan there are more models for distance education. Which one should be used depends on many factors i.e. the organisational structure of the educational institutions, the needs and the market in the country, the programs that are taught and the available infrastructure. In our case, the Faculty has to start from very beginning, meaning that the project needs as much as possible support from the educational institution that has experience in education and available organisational infrastructure. For that reason a project committee was set that consisted from members of educational staff, members from the financial service, the administration centre and from the publishing unit of the faculty. It was decided that this activity in its very beginning should stay as a part of the educational institution. The tasks were allocated to different members of the project team as follows. The organisational part of the education in the DLP (Distance Learning Project) was responsible for the promotion in the public media of the new type of study, consulting services in relation to the registration and matriculation of students, collection of registrations and fees. The other organisational part of DLP was concerned with the preparation of the lecture scheduling, preparation of the study material, organisation of the tutorial work, organisation of exams. Besides that, some activities that provided support to the project itself were also envisaged such as: handling data about students, tutors, electronic publishing desk and other information about DLP.

The next step was the evaluation of the students possibilities to access the Internet and the information infrastructure of the faculty. The responses were quite encouraging as 50% of the students reply that they have access to the Internet. For the rest educational centres were designed in every bigger city in the country. A person (employee) with task to care for the administration of such centre was envisaged. It was agreed that the administration in the educational centre will use the existing application for administration at the University of Ljubljana (FINISD). The application was designed for the Novell network systems and uses the IPX/SPX protocol. The publishing unit at the Faculty was invited to investigate the possibilities for publishing of the study material on digital media.

4. Setting up the Infrastructure

The existing information infrastructure was not in very good state. The national infrastructure of the academic and research network was just starting with its activities in the interior of the country from where the majority of the students that work were from. It was evident that the existing infrastructure where available should be used and were not available a new one should be developed. The project team realised that the existing infrastructure should be evaluated first and then the best solution for improving the existing infrastructure or setting up new parts should be selected. Two models for building up the infrastructure were used: the so called the model of the basic services and the optimal technical model. The model of the basic services was based on very cheap solutions which guaranteed only the basic services required by the DLP. The other model contained the solutions that provide best technical solutions in the context of the needs of the DLP. The choice which one to be implemented depended from the funds allocated for setting up the infrastructure and the first year needs of the DL educational process. The number of educational centres set up in the first year was relatively small i.e. only 3 such centres were established in the country due to the low number of students in the first year of such study. That was sort of an alleviator circumstance.

Both model were evaluated in the light of different criteria such as: reliability of the network, meeting the needs of DLP, the speed of data transfer and communication, the possibilities for further development of the network, security and data protection, cost and benefit. A comparison table was generated for both model and the solution that was chosen was the model of basic services. The topology of both models will be presented on Fig1, Fig.2 and Fig3. The technical optimal model was developed as a model with 2 options. In the first the basic infrastructure of the academic and research network is used in the second leased elastic lines from the national Telekom were used.

When the evaluation was finished , the building phase of the infrastructure followed. The type of connectivity was selected as well as the type of the servers and the type of the application software.

5. Instead of conclusion - Experiences and Lessons Learnt

It was quite evident from the first year of such type of education process that the students get accustomed very quickly to the use of the network and the basic services such as use of electronic mail for communication and the access to the WEB services. The transfer of educational material was not a problem too. The major problem appear to be the communication to tutors who do have attitude for use of the network regularly and are repulsive towards the new technology. Other problem appear to be the lack of facilities for video-conferencing (lack of equipment and bandwith) and other types of multi-media educational material. That requires further steps in the development of DLE.

How Are Students Doing in an Online Course?
A Case Study of Factors Affecting Students' Online Discussions

Mingming Jiang, Center for Learning and Technology, SUNY, US mjiang@sln.esc.edu

Carla Meskill Educational Theory and Practice, School of Education
SUNY Albany, US Meskill@cnsvax.albany.edu

Abstract: This paper presents a case study of student and instructor interaction in an online course, Computers and Society. Through our initial analysis, we found that well-defined problems, questions, and issues elicited more and longer student responses than did those whose focus was less clearly stated. We conclude that in an online course, clarity helps alleviate student disorientation and focus student attention in the face of overwhelming numbers of online messages.

Introduction

Ideally, an online environment is interactive. It encourages active involvement and facilitates co-construction of meaning (Harasim, 1990). Participation stimulates cognitive restructuring through response to new information, agreeing and disagreeing, and challenging. One objective in a an online course is to engage students in these kinds of constructive conversations through building a student-centered environment.

This paper reports preliminary results of an analysis of student and teacher interaction in the online course, *Computers and Society,* taught by Frieda Mendelsohn. This course was delivered in the summer of 1996 through the State University of New York Learning Network, a project that offers several online college courses for alternative students. Seventeen students enrolled in the course which consisted of four types of learning activity: 1) responding to discussion questions; 2) critiquing an article; 3) presenting an issue; 4) presenting a final project. The first three tasks required student participation in online conversation. The fourth was a paper that students mailed to the instructor. Our analysis was based on the first three conversation-based activities.

Online Discussion

Our initial analysis of course data (records of all student and instructor messages) indicates that responses to the instructor's questions and to other students' critiques or the issues they raised were not evenly spread out. Why did some documents attract more and more developed responses that others? By undertaking a content analysis and comparing the kinds of discourse that attracted student input with those that attracted little or none, we found that clarity of questions and statements seemed to play a critical, determining role in whether and how much students contributed to a particular discussion.

For example, in Course Module I, the instructor posted four questions to initiate discussion. The first question began with the general statement of a problem (controversy surrounding the Information Superhighway), then narrowed the question down to a fine-tuned level of specificity. Finally, students were asked to list the kinds of cultures inhabiting the Internet and the resulting clashes between these groups. This question was well developed, concise, well-focused, to the point, elicited student opinion based on fact, and contained no distracting information. It elicited forty-four student responses. The second question, which attracted twenty-four responses, asked students to express their personal opinions of a course textbook question. The question concerned the author's concern that "teenagers have moved on to new delights". The instructor accompanied the question with two examples of teenage enchantment from the *New York Times Cyber Times* and asked students to react. Following were two notes with instructions for accessing this online publication and other pertinent sources. It seems that the core question became overshadowed by this abundance of subsidiary information and, consequently, its focus was lost to students. Though we cannot directly attribute this radical decrease in student responses (nearly 50%) to the density of the question itself, this highlighted the probable influence of question structure on student responses. The third question, moreover, which asked students to define cyberspace and state important questions concerning its influence in the future - a decidedly narrow and specific task, produced thirty responses.

In Module II, students posted their article critiques. Nine articles were selected and from these students produced sixty critiques. Some of the article critiques attracted multiple peer responses, while others stimulated none. Analysis of ten critiques selected for high response and low response indicated that a clearly presented viewpoint tended to elicit more and longer reaction than did cloudy ones. In one case where a student patently and vehemently disagreed with the author of an article on software environments and very carefully articulated his viewpoint, a lively, lengthy exchange ensued.

Clarity appeared to play an even larger role when students presented the issue of their own choosing in the third assignment. Again, there was a wide range in the number of responses based on how carefully the issue was expressed. The number of responses ranged from twenty-nine per issue to none at all. In comparing the most productive issue presentation with those that produced less response, it was clear that the manner of presentation and the number and quality of responses were parallel. The issue presentation that brought on the most student response (nine response layers) was well constructed and carefully laid out both sides of the issue selected: federal regulation of the Internet. By contrast, presentations that elicited a small number or no response lacked clear definition of the issue and failed to lay out both sides.

Conclusion

In an online course, a student is required to log on three times per week. In the intervals between log ons, multiple messages and threads of conversation have become part of the course environment. Numerous new documents from the instructor and other students are therefore on the screen each time a student logs on. Weeding through these documents and making sense of them is a time consuming task. It may be that by nature we are simply attracted to what makes the most sense with the least amount of effort; e.g., clearly stated questions, problems, and opinions.

Based on this case study, it is impossible to draw definitive conclusions regarding the relationship between clarity of presentation and the amount and quality of online discussion it provokes. Common sense would dictate that the clearer one is in articulating questions and opinions, the easier it is for one's interlocutor to respond. In the classroom we have the advantage of multiple, real time turn taking along with all the powerful intricacies of non-verbal face-to-face cues we make use of when negotiating meaning. These dimensions of communication play a critical role in supporting and clarifying our oftentimes messy oral discourse. Online, this is not the case. Clarity of expression, therefore, takes on much greater importance in electronic forms of teaching and learning discourse.

Making the Transition From Traditional to Web-Based Course Material

Bradley F. Johnson
University of Calgary
2500 University Drive
Calgary, Alberta
T2N 1N4
email: bfjohnso@acs.ucalgary.ca

Abstract

Structuring traditional course material for presentation via the Internet appears to be causing confusion as to who does the structuring and what should appear on the Internet. Instructors are often given the responsibility for structuring their material and determining the types of activities that should be supported without a working understanding of what a web-based course presentation would look like or work like. What is described in this paper is a methodology and a conceptual tool for helping instructors bring their course 'on-line'

Introduction

The conversion of traditional lecture based course material to Web based material is bringing to light a number obstacles. Specifically, it appears difficult to structure existing material to take advantage, even minimally, of an Internet-based presentation of the material. It is hypothesized that the reason for this originates in the imposition of a steep learning curve. That is, instructors must learn 1) how the web works, 2) what activities to support, and 3) how to structure hyperlinked presentations. This paper will describe the problem and the proposed solution.

The Context

The Distributed Education Unit (DEU) at the University of Calgary provides web-based course support for the Department of Community Rehabilitation. The mandate of the DEU is to provide technical support in terms of hardware and software and to provide leadership in the area of Internet based provision of course material e.g. distributed education. The expectation was that instructors, being the content experts, would structure the course material prior to submission to the DEU leaving the task of converting the material to web-based material to the staff of the DEU. What was found, however, was that many instructors were providing their regular course material without structuring it in any way. This placed the DEU staff in the position of attempting to structure material without benefit of content knowledge and to determine what sorts of activities would support the material. In other words the staff of the Deu were expected to fulfill roles of content experts and instructional design. While the latter may have been within the purview of the DEU, the former clearly was not.

Problem Definition

Traditional course material consists of course notes, lecturing, overheads, perhaps movies, and, of course, tests. A high level of interaction within the material (hyperlinking) is possible. That being said, however, not all material nor high levels of hyperlinking, should be used in web-based presentations.

Traditional classroom and instructor-student interaction involve communication modes including, most often Face-to-face (FTF) or voice, and increasingly, email. Activities that involve group work are also part of many traditional classrooms. Student activities also include peer interaction.

There is often a desire to support as many of the traditional activities as possible without a clear understanding of what that support would look like. Instructors are faced with the dilemma of selecting material for a medium of which they have little knowledge.

Problem Solution?

In order for instructors to structure their course content for Internet presentation they must know something of the way in which web based pages, and the Internet, go together. That is, they must have a working understanding of how their material will look and how students will interact with it, and most importantly, the limitations of web based pages.

A means of flattening the learning curve has been devised that should serve to assist instructors to structure their content for an Internet based presentation. The learning tool being developed consists of an informational booklet that outlines the various services offered and a detailed example of the process involved in preparing a course for a web-based delivery. A task analysis, on a course by course basis, of what both students and instructors do while engaged in a course helps to structure or provide conceptual tags with which to build upon. The next step is to begin building a room metaphor around the task analysis i.e. where do these activities take place. Once the room metaphor has been sketched out it becomes possible to show how some hyperlinking may occur (see Figure 1). It is possible at this point to illustrate the demands of each type of room. For example, lecture rooms may be primarily text-based with some limited visuals. Interactive rooms, such as a student lounge area, may demand some way for students to interact. This metaphor helps to define what is needed from the Internet-based material and provides an opportunity to explore what is possible using Internet-based material.

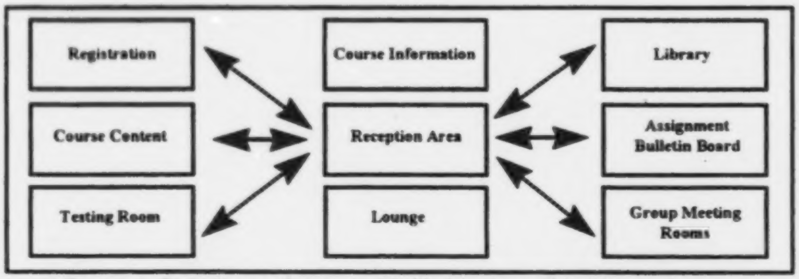

Figure 1: Sample set of rooms with likely subset of linking pathways.

Once the rooms have been clearly defined and discussed it becomes possible to have a look inside each room. What, for example, would one find in the library? Thus an opportunity is awarded to 'sort out' or structure course material with an eye towards which room the material belongs and how it may be linked together. Furthermore the constraints of an Internet based presentation, as well as the possibilities, help structure the material in interesting new ways.

Conclusion

This project has only just begun and so represents a work-in-progress. Over the next year this instructional technique will be used both on an individual basis and with groups. Efficacy will be judged by comparison of current problems with those of a year from now as well as ongoing feedback from instructors and students.

Development of Interactive, Multimedia Educational Software for Studying Native American Cultural History and Foreign Languages.

Linda Jones
Department of Foreign Languages
University of Arkansas
Fayetteville, Arkansas, USA
lindaj@comp.uark.edu

Abstract: Faculty at the University of Arkansas are developing interactive multimedia educational software modules for students at junior high, high school and college levels. The purpose of this software is to give students an opportunity to learn a foreign language and to learn about Native American and European encounters in the Lower Mississippi Valley in the 17th and 18th centuries. With this software, students will have the option to move through three different learning levels to gather the information and skills needed to better understand foreign languages and to better explore ethnohistoric events of the past. The program will follow an "interactive spiral effect" as introduced in [Kozell 1996]. Such an effect will invite students to explore various activities and materials in one level, and will invite or "entice" them to learn more in the next. The program is currently under development and will be finished by the year 2000.

Picture this! You are working at your computer and suddenly you see an authentic 17th century French document of the encounter between the Quapaw Indians of Arkansas and French missionaries from Québec. But, there's more; you click a button and view a simulated movie of this event along with narration, maps, pictures, Arkansas River mud, live alligators snapping at your heels and...well, I am getting a little carried away, but nevertheless, exciting things are happening at the University of Arkansas-Fayetteville! In September 1996, the Department of Foreign Languages at the University of Arkansas and the Arkansas Archeological Survey were awarded a grant in the amount of $180,000.00 from the National Endowment for the Humanities to develop interactive, multimedia educational software (CD-Rom and World Wide Web platforms) for students at the junior high, high school and college levels. Since the grant was awarded, faculty from both departments have begun work on the project which, when completed, will offer students opportunities to learn French and/or Spanish while studying the history of Native American encounters with Europeans, African-Americans, and Euroamericans. The main focus of the project is on Native American encounters in the Mississippi Valley. This region, including Arkansas, was chosen because it witnessed a greater range of cultural encounters, involving English, French, and Spanish colonists and dozens of distinctive Native American groups, than is the case in many other New World settings.

For this project, we are using cross-platform authoring software packages, (Macromedia Authorware and Director), which bring a maximum amount of flexibility and creativity to the forefront. With this software, we are able to design an active learning structure which will enable students to acquire knowledge and to develop critical-thinking and problem-solving skills relevant to the humanities in general and, more specifically, to the disciplines of foreign languages, anthropology, geography, history, and social sciences. As we work on this project, our goal is to organize it in such a way which will allow software users to navigate through modules representing increasingly challenging levels that range from introductory presentations of basic concepts and learning skills to opportunities to analyze data sets and to complete problem solving tasks relative to cross-cultural communication and interaction. The project itself will have self-directed interaction with texts (including authentic foreign language historical documents), maps, graphics, animation, sound, and interactive exercises to interpret the events in the Mississippi Valley during the early stages of colonization. Since we are developing both CD-Rom and World Wide Web modules, instructors will have multiple means to use computer technology to teach students how to use information from archeological and historical sources to learn a foreign language and/or to learn about Native American cultural history. Once the program is completed, we will not merely provide students with a multimedia encyclopedia, but will help them to develop the skills that are necessary for creative inquiry and problem-solving in the humanities.

We anticipate designing 5 modules for this three year project. The template for these modules will contain three different educational levels. For example, in Level 1, basic concepts relative to a given module's content are introduced with activities suitable for illustrating those concepts and developing basic learning skills. In Level 2, more detailed information is provided along with opportunities to apply critical thinking and problem solving skills. Here the emphasis is on knowledge building, information evaluation and problem solving activities. In Level 3, advanced information and tools are provided to help users to create and analyze data sets. Using this template, students will have several modules from which they may choose, each surrounding an actual historical event or circumstance.

Students will also have the option of studying the material in French, Spanish or English. For example: Students select the "Interactions" module in the French language. In this module, the students explore historical documents and compare and contrast Native American and European views of contact and interaction to enhance their understanding of the issues of intent, expectation and outcome in situations of cross-cultural communication. Two encounters are discussed here: The first, the 1699 calumet ceremony performed for Father Davion by the Quapaw which was a friendly offering shared by both cultures; the second, a 1729 encounter between the Jesuit Missionary Paul du Poisson, and the Quapaw, which provides a contrast in that du Poisson rejected the offering of the calumet, a symbol of alliance, because he did not want to reciprocate the Indians' offer with a repayment of gifts.

In Level 1, students work through basic language exercises which allow them to hear and to see short French phrases, accompanying pictures, and a map of the region indicating the locations where the encounters took place. Simplified texts and illustrations of selected Native American and European greeting ceremonies are provided with exercises that prompt users to identify the settings for these ceremonies, their participants, the objects used and major elements of the ceremonies. After working through the exercises, various comprehension questions follow to verify basic understanding. The global question is Why? Why was one encounter successful and the other not. Students are invited to hypothesize and to explore further information in Level 2.

In Level 2, students review additional information, in French, on Native American and European rituals and their cultural meanings. Screens and dialogue boxes provide exercises in which specific elements of ritual performances can be matched with their associated cultural meanings. Users can compare and contrast the meanings of several ritual performances to identify similarities and differences in the views of several Native American and European groups. At this level, students are able to access many Level 1 features such as vocabulary and comprehension checks. Users hear and see again the information from Level 1 but are now provided with new exercises which permit them to identify Native American and European objectives and common problems affecting participation.

In Level 3, students obtain richer historical and cultural information about these encounters and view the authentic historical documents containing information on subsequent encounters and interactions among the participants in the greeting rituals previously examined. Here users can employ interactive tools to develop second language reading skills, and/or to create new data sets of examples of Native American and European expectations and outcomes following the previously-concluded greeting rituals. Resolution at this stage is achieved by using tools provided to organize, format and print or download the selected texts and/or data sets.

Aside from the modules developed for this project, there will also be links to various on-line sources for in-depth, university level study of the cultural and historical settings and events in the Mississippi Valley. Once the project is completed, the two versions of the program (CD-Rom or World Wide Web) will be available to schools free of charge.

The learning process can perhaps be most effective by teaching across the curriculum, where information is provided and basic learning and thinking skills are acquired across a variety of related subject fields, rather than on a subject by subject basis. As a result, students will become better able to grasp connections among separate bodies of knowledge and will better understand the relevance of alternative perspectives and multiple points of view. Because of the integration of foreign languages and anthropology in our project, we strongly feel that this combination will provide a holistic environment in which foreign languages and historical and cultural materials can be combined to enhance the learning process in each subject area. And too, this approach (using the World Wide Web/CD Rom) will bring rare, exciting and yet important information to students, teachers, interested viewers and colleagues who otherwise may never have an opportunity to explore authentic texts, graphics or events of the Lower Mississippi Valley.

The Animal Diversity Web

Tricia Jones, Office of Instructional Technology (triciaj@umich.edu)
Philip Myers, Museum of Zoology and Department of Biology (pmyers@umich.edu)
Roger Espinosa, Office of Instructional Technology (roger@umich.edu)
University of Michigan, Ann Arbor, MI

Abstract: Since January 1995, faculty curators at the University of Michigan Museum of Zoology have taught an innovative undergraduate course: Biology 108, Introduction to Animal Diversity, intended for students who are not Biology majors. To support this course, we have created the Animal Diversity Web (ADW), a tool for (1) teaching post-secondary students about the ecology, biosystematics, and conservation biology of animals; (2) using inquiry-based learning to teach students general patterns and principles in these fields; and (3) improving students' knowledge of what science is & how it works.

1 Instructional Problem

There are two special problems created by the format and content of *An Introduction to Animal Diversity*. First, non-major students do not want or need highly technical descriptions of the animals they study. They are more interested in – and as voters, will have an impact on – conservation, natural history, and areas of ecology and evolutionary biology that provide the scientific foundation for environmental biology. We have been unable to find a textbook that takes this approach. Second, because this course is taught by a ten or more lecturers (each a specialist in a different aspect of biological diversity), continuity is a problem. Lecturers differ in style and emphasis. We needed a means of providing a consistent nucleus of information about each group of animals. This problem was especially acute because we lacked an appropriate textbook.

2 Solution: The Animal Diversity Web

A collaboration between the Museum and the ITD Office of Instructional Technology explored emerging technologies to help solve this problem. Those discussion quickly focused on the possibility of using the World Wide Web. The result, much modified, honed by two years of experience with classroom use, and ever-growing, is the Animal Diversity Web (ADW).

2.1 Scope

The nature of the World-Wide Web is very well suited to the hierarchical nature of animal classification. The ADW itself consists of three components: a large collection of images, species accounts describing individual species, and characterizations of higher level groups such as phyla and classes.

For each group, we provide information in the form of both text and images. Descriptions are provided at higher levels of classification (Phylum, Class, Order, Family) and at the species level. At the bottom level of the ADW are species accounts (such as the gray wolf or the moon jelly), providing details of distribution, natural history, economic importance, and conservation, and when available, a photograph. They are prepared for individual species using a standard format; currently, we have around 800 such accounts.

Because our experience with animals is primarily visual, a collection of high-quality pictures is critically important to the ADW. Currently, it includes approximately 1000 images. Many of these were taken from our own collections of color slides. Other images are taken from commercially-available CD-ROMs, Internet sources (the Smithsonian, for example, provides a large number of images for non-commercial use), and in some cases from sources such as textbooks where we have purchased the right to use the pictures (the latter category is only available to users in the .umich.edu domain).

The images depict animals representing nine Phyla. These Phyla were chosen because they contain >99% of all animal species and because they are most of the Phyla discussed by our lecturers. We have written text describing each of these Phyla, and in addition, at least 40 Subphyla and Classes. The section on mammals is most complete. Here, we have around 250 images representing approximately 230 species. These show examples of all 21 Orders of Mammals and nearly 100 Families. Text has been prepared to describe all Orders and about 50 Families.

2.2 Structure

The ADW, like animal classification itself, is hierarchical in structure. Students navigate through it to find information using four methods: the taxonomic hierarchy, shortcuts to major groups discussed in class, a search form, or a visual representation of the structure.

The search form is based on the same structure as the individual species accounts. Users can search for a specific account not only by the animal's common or scientific name, but by combining other characteristics as well. For example, after reading about the gray wolf, a student might wonder, "Are there meat-eating mammals who are not in the Carnivore Family? How many?" Another might wonder, "What other animals exhibit pack behavior?" Both of these questions could be explored within our structured search tool, by specifying appropriate criteria for the various categories of interest (food habits, family, behavior, etc.).

2.3 Student Participation

Students actively participate in the creation of the ADW by writing species accounts. Students in Biology 108 choose two animals (one vertebrate, one invertebrate) to research. Their research is scaffolded by the Species Account Template. The template (created in SuperCard) provides a series of fields and checkboxes to ensure that student-written accounts cover the appropriate topics in a standard format. Students also use this template to electronically submit their species accounts.

Students respond enthusiastically to this assignment, as it allows them to apply the terms, concepts, and big ideas they learn in lecture to a specific animal of their choosing. Because accounts are published on the Web, they have an authentic audience for their work. In addition, students in the class participate in peer review of one another's accounts. This process has dramatically improved the quality of the species accounts, by reinforcing the presence of an authentic audience. Final review (for accuracy) is done by the professor for the course and teaching assistants before accounts are incorporated into the ADW. (Additional technical details on site infrastructure can be found in the CD-ROM version of this paper.)

2.4 Inquiry Assignments

While some students are fascinated by the ADW and explore it thoroughly, other students need to be encouraged to take advantage of the resource. The search feature of the ADW helps meet this goal. This capability can be the basis for an enormous variety of questions, limited only by the information in the species accounts. Example assignments include the following:

- Consider bats who eat fruit and those who eat insects: How are they similar in terms of size, gestation length, and geographic distribution? Different?
- Do endangered species tend to be concentrated in certain parts of the world? To be especially large or small in body size? To belong to a particular trophic level?

These questions are very well suited to small discussion sections. They require information gleaned from a large number of species accounts, so a group of students can collaborate to answer them. The questions get at some of the most fundamental concepts taught in the course. They force students to synthesize, not simply regurgitate.

3 Importance of the Animal Diversity Web

As it exists today, the ADW is a cornerstone of instruction about biodiversity. Currently, it serves Biology 108 and other classes at UM, and has daily visitors from around the world. The benefit of the resource is directly linked to the scope of the collection. The ADW provides students with ready access to images of animals and to text that emphasizes natural history and conservation. Combined with the searching function, the ADW has also proved to be an exceptional tool for teaching general concepts in ecology and evolutionary biology. In part this is true because it allows us to illustrate these concepts with a rich library of examples. More importantly, with properly framed questions, we can lead students to explore natural history in a way that permits them to discover basic principles for themselves. The ADW facilitates the presentation of information, but it also allows us to give assignments that force students to search for patterns and synthesize information that crosses the usual lines of animal classification.

4 Acknowledgments

The Animal Diversity Web has been created in a collaboration between the University of Michigan Museum of Zoology and the Office of Instructional Technology (part of the Information Technology Division), with funding from the College of Literature, Sciences, and the Arts.

Design of a Virtual University in a Korean Context

Insung Jung
Institute of Distance Education
Korea National Open University, Korea
E-mail: isjung@av9500.knou.ac.kr

Abstract: The purpose of the virtual university in general is to expand access to higher education for individuals scattered all over the world, to remove barriers of time and space, and to develop a cost-effective approach that provides an interactive learning opportunity for adults. The Korea National Open University launched a two-year project to design a virtual university in the Korean context as suggested by the Presidential Commission on Education Reform in February, 1996. Purpose, structure, programs and delivery modes of the virtual university are outlined along with the nature of the university.

Introduction

With the development of new information technologies, the idea of a virtual university has been realized to bring wider opportunities to people in the form of flexible, open and distance learning system. Among these information technologies, satellite TV, video-conferencing, and high-speed computer networks - including the Internet - have been adopted as major interactive media to deliver courses at these virtual universities. The purpose of the virtual university in general is to expand access to higher education for individuals scattered all over the world, to remove barriers of time and space, and to develop a cost-effective approach that provides an interactive learning opportunity for adults.

Teaching at a distance in Korea began with the founding of the Korea National Open University(KNOU) in 1972. In 1996, KNOU launched a two-year project to design a virtual university in the Korean context as suggested by the Presidential Commission on Education Reform in February, 1996. The Presidential Commission on Education Reform, has defined the goal of the Korean Education System in the 21st century as an "Edutopia", a utopia of education. As one means of realizing an Edutopia in Korea, the foundation of a virtual university was suggested. KNOU has taken the responsibility to participate in designing this virtual university.

Concept of a Virtual University

Virtual universities in the world can be categorized according to their uses of different media. Some universities such as National Technological University in the USA use satellite TV for delivering courses and the Internet for interaction. Other universities such as Virtual Online University use the Internet and other multimedia as their main delivery and interactive devices. There are some institutes which use the Internet only. All these universities deliver their courses beyond the walls of the traditional university classroom and move the campus to the cyberspace horizons.

Virtual university can be described as a higher education system that adopt computer and telecommunications technology to organize, develop, manage, and administer learning. Limitations of space and time restrictions can be disappeared in a virtual learning environment. If synchronous instructional activities are needed, various types of teleconferencing technology can be used. A virtual network of students, instructors, administrators and information is established on the basis of the development of information technologies.

Design of a Virtual University

Purpose

A virtual university in a Korean context is seen as an alternative form of existing higher educational institutes, which will broaden the range of higher education opportunities for the people of Korea. And indeed, one's credits earned through the virtual university will be saved in the National Credit Bank to be awarded appropriate degrees or certificates. The virtual university will also contribute to reduce the costs of providing higher education opportunities to adult learners by adopting information technology and sharing educational resources.

Programs

The services of the virtual university have to be market-oriented, learner-centered, degree-granting, high quality, and cost-effective. The lifelong learning needs of adults will be assessed to provide flexible innovative courses. Credit courses, non-credit courses, certificates of specialization and degree programs at undergraduate and graduate degree levels can be offered at the virtual university.

Structure and Function

A central cyber-office of the virtual university will offer administrative and managerial services including the development of courses, the maintenance of academic records within the system of the National Credit Bank as well as financial management of the institution. The virtual university will cooperate with existing colleges, universities, training centers and other post-secondary education institutes in developing its courses. The faculty members and instructional designers of the virtual university will have a primary responsibility for developing virtual courses. There will be several schools in the virtual university, each with major programs.

Regional study centers will be housed in 41 study centers of the Korea National Open University, public libraries, local colleges and universities to provide distance learning courses and support services to the students of the virtual university. By on-line or personal tutors, systematic support for individual students will be provided as forms of monitoring, evaluating and reporting academic progress throughout each course.

Course Development and Delivery Mode

Course or program providers for the university will be solicited throughout the nation. The programs of the virtual university will be provided primarily by institutions of higher education and private training sectors in Korea and other countries. Nationally recognized experts in their fields of study can be engaged as creators of courses and curricula.

The primary delivery modes of instruction will be computer-mediated communication system including the Internet and CD-ROM. Video-conferencing system will provide opportunities for real time interaction.

An Intelligent Hypermedia Teaching System for Chinese Language Learning in Primary School

Abstract: This paper describes an intelligent hypermedia teaching system for Chinese language learning in primary school and shows the design and implementation of four important models in this system,including main learning environment , hypermedia knowledge-base, student model and intelligent navigator. The purpose of developing this intelligent hypermedia teaching system is to survey the impact on Chinese language learning resulted from appearing of intelligent hypermedia and to attain some experience for developing such intelligent hypermedia teaching system.

Introduction

An intelligent hypermedia is a new information technology which combines both AI technology and hypermedia technology together. An intelligent hypermedia teaching system integrates the advances of both the ICAI and the hypermedia system and eliminates their defects.

Now we are developing an intelligent hypermedia teaching system for Chinese language learning in primary school. Our purpose is to survey the impact on Chinese language learning resulted from appearing of intelligent hypermedia and to attain some experience for developing such intelligent hypermedia teaching system.

Overall Design of the System

According to learning regularities of Chinese language. this system provides the students two learning environments: One is the main learning environment which shows the students hypermedia language material. another is the subsidiary learning environment which is actually hypermedia knowledge-base.The students can enter any learning environment. The main learning environment is the main interface between the students and the system. The students can do exercise in the main learning environment. And if they encounter some difficulty ,they can jump to hypermedia knowledge-base to learn furtherly. Those errors made by the students are saved in the student model and will be diagnosed in order to generate remedial strategies. The selection of learning material , instructional objectives and type of exercise is not decided only by the computer tutor. The students can participate those dicisions in order to make proper selections.

The system contains four important models which are described as following: the main learning environment, hypermedia knowledge-base,intelligent navigator and error diagnosis model.

Design of the Main Learning Environment

The main learning environment is used to show language material. Those language material are organized in form of hypermedia in order to provide the students active interface. There are two kinds of object in the learning environment: objects for learning and objects for activating. In the main learning environment the student can do some exercises. The system selects proper questions ,which can be either generated automaticly by the system or provided by an external questions base,according to the student model.

Design of Hypermedia Knowledge-base

In the hypermedia knowledge-base ,the knowledge is represented by structural nodes and links. Here the structural node is defined as two parts:type of node and knowledge-slot list. The type of node is defined as (name of type,value of type). Knowledge_slot is defined as (attribute name ,attribute value). Different from traditional hypermedia system, the links in hypermedia knowledge-base is also structural. A link structure contains starting node,ending node, name of link,types of link,attributes and link functions.

Student Model and Error Diagnosis

Out structure of student model contains sevel parts as following :The index to instructional objective unit to attain: The degree of attaining current instrcutional objectives: A wrong knowledge unit list; The type of question met already and number of exercises which have been done; History record of navigation in hypermedia knowledge-base; Record of language material learnt by the student; Some nonintellect factors,such as age,sex,some flags(such as background music,playing speed of video,sound volumn etc.) needed by the student in the learning environment .

Error diagnosis is the most important and the most difficult model of the system. We are building more efficient grammar and semantic knowledge-bases of Chinese language to detect error made by sudents.

Design of the Intelligent Navigator for the Hypermedia Knowledge-base

The intelligent navigator for the hypermedia knowledge-base has some special functions: informatin filter,position marking and effective guide and answering questions.

Interactive 3-D Physical-Simulation Environment in a Virtual World

Susumu Kakuta, Akihisa Kawanobe, Yasuhisa Kato, Katsumi Hosoya
NTT Information and Communication Systems Laboratories
Tokyo, Japan
E-Mail: kakuta@isl.ntt.co.jp

Abstract: This paper describes a method for achieving an interactive 3-D physical simulation environment in a virtual world using the Java language. The simulation environment is constructed of generic and basic Java class objects, such as environmental properties, object properties, simulation engines, and interactions between objects, which can be reused and make the simulation environment more extensible. In this application, students can conduct basic experiments, such as observing balls falling and bouncing on a floor and their motions after colliding with each other.

1. Introduction

Self-discovery learning using interactive learning materials has become an important topic in the field of computer-aided instruction (CAI). Example of such CAI systems are the Interactive Learning Environment (ILE) and Micro World [Okamoto, 1994]. Several Micro World systems have been developed for both 2-D and 3-D interactive physical simulation, for example, Interactive Physics [Interactive Physics 1997]. In these simulation environments, learners can change property parameters interactively, but the environments are not extensible because they are implemented using a compiler language, such as C or C++. Therefore the experiments that can be conducted are limited by the system integration. In this paper, we propose a method for achieving an interactive 3-D physical simulation environment in a virtual world which is extensible using the Java language.[JDK 1996].

2. Use of 3-D physical simulation environment in a virtual world

An interactive simulation environment in a virtual world functions as a virtual science laboratory, much like a real one in an elementary or junior high school. This type of environment enables users to perform various virtual experiments. They can change the parameters interactively, including both the environmental properties such as gravity and objects' properties, such as their initial velocity, initial position, acceleration, and resiliency. Users can predict the results of changing the property parameters, then run the experiment and watch the results on the screen immediately. Users can also "walk through" the 3-D virtual world in which the simulation experiments are performed, enabling them to observe the phenomena from various viewpoints.

3. Implementation

3.1. Software used Java

Java is an object-oriented, interpreted, secure, architecturally neutral, portable, and dynamic programming language developed by Sun Corporation. Java describes applications by using class libraries in much the same way that C++ does. Java is quickly spreading in the field of programming and is expected to support 3-D graphics in the near future. We built our 3-D physical simulation environment as a Java application, instead of using C++, to make it more portable and architecturally neutral. Consequently, when a new version of the application is released, only the class objects constituting the new parts of the application will need to be downloaded to the client site instead of replacing all the binary file.

3.2. Java object structure

We have defined five kinds of Java class objects in order to achieve a more extensible and interactive 3-D simulation environment. Because Java class objects are defined independently of each other, users can easily define new environments, simulation engines, and interactions between 3-D objects by creating a new Java class object inheriting and combining the basic class objects. Each Java class object for describing a simulation can be used with any viewer that supports the Java application program interface (API).

1) Class to define a viewer.
2) Class to define environmental properties.
3) Class to define 3-D object properties.
4) Class to define simulation engines.
5) Class to describe interactions between 3-D objects, such as collision detection.

We will describe these five kinds of classes in detail in the following.

1) Viewer: We defined a "Viewer" class to display 3-D objects from the users' viewpoint. Methods in the "Viewer" class are implemented as native methods using the WorldToolKit [Sence8, 1993] C library for visualizing 3-D graphics because Java does not yet support 3-D graphics library. The WorldToolKit C library has task functions, to realize simulation in a 3-D space, that can be connected to individual 3-D graphic objects and can be defined by users. However, the simulation is limited when using only these task functions because the WorldToolKit is a C library. A more extensible simulation environment can be created using Java. When a Java 3-D graphics library is released, we will redefine the "Viewer" class to use it; the viewer can then be a Java applet downloadable and executable on a World Wide Web browser.

*2) **Environmental properties:*** We defined a "SimulationEnv" class to encapsulate the variables for the environmental properties: *gravity, simulation start time, current time, previous time*. This "SimulationEnv" class encapsulates only gravity in the current version. The "Viewer" class is defined as a subclass of the "SimulationEnv" class, so it inherits the environmental properties. The values of the environmental properties are set as default values when the viewer is generated, but can be changed by users interactively.

*3) **Properties of Simulated 3D object:*** We defined a "Simulated3DObject" class to contain the 3-D object properties needed for physical simulation: *mass, resiliency factor, previous/current position, previous/current orientation, previous/current velocity, previous/current acceleration* . Each property has a default value that is set by users interactively.

*4) **Simulation engine:*** A simulation engine is defined as a behavior class. In our first implementation, we simulate 3-D objects falling in a gravitational world. The simulation engine classes are instanced within the block of the 3-D object class. A simulation engine is activated by invoking "start()", which is a method of the simulation engine class with an argument of start time. The Viewer has a timer and calls the "simulate()" method of 3-D objects with arguments of previous time and current time. The "simulate()" method of a 3-D object runs the simulation engines. A simulation engine calculates the current position, orientation, velocity, and acceleration in each direction of the 3-D object and returns the values. The simulation engine classes can thus be used in other viewers that support Java API. The 3-D object is set to the correct position and orientation according to the values returned from the simulation engine. The engine ignores interactions with other 3-D objects, such as collisions. Collision detection is checked by another class object. We have initially implemented the "Fall" class, which simulates the motion of falling.

*5) **Interaction between 3-D objects:*** Collisions are the main interaction between 3-D objects in the physical simulation environment. A class object is therefore needed to describe the motion of 3-D objects before and after collisions with each other. We have defined classes to describe interactions between 3-D objects as follows:

- The "DetectCollision" class is defined to check if two objects collide with each other.
- The "KeepEnergy" class is used to calculate the velocity, position, and orientation of each object after the moment of collision. There are two cases for two 3-D objects colliding:

  (1) Both objects can move, such as "ball".

  (2) One can move and one is static, such as "ball and floor".

  The 3-D objects are checked for their ability to move, and the results are returned to the calculation.
- The "CollectCollidingObject" class is for collecting the position and orientation of each object after colliding with another object. First, the position, orientation, and velocity of each object after the moment of collision are calculated by the "KeepEnergy" class object. Then the current position, orientation, and velocity of each 3-D object are calculated and the values for the 3-D objects are set accordingly.

The classes for describing interactions between 3-D objects are called within the "Viewer" class. The 3-D objects to be checked are selected by the users before starting a 3-D physical simulation experiment, and the classes check on only the selected objects.

3.3. Example simulation experiment

Based on the classes we have defined, the motions in a gravitational environment are as follows:

- Motion of falling ball.
- Motion of ball bouncing on a floor.
- Motion of two balls colliding with each other.

Users can experiment by changing the properties of the 3-D objects, such as the resiliency factor, initial velocity, and initial position, and also the environmental property (gravity).

3.4. Reusability and extensibility

In the current version, the simulation environment has only gravity as an environmental property. The environment can be easily extended by adding other properties (air resistance, electrostatic fields, and so on) that inherit the basic class object we defined as "SimulationEnv". By combining the classes of interactions between 3-D objects, various simulations can be run. They can be also reused to create a new class of interactions between 3-D objects.

4. Conclusion

We presented a method for achieving an extensive and interactive 3-D physical simulation environment in a virtual world using the Java language. In the application we developed, learners can conduct simple 3-D physical simulation experiments. The "Viewer" class has a native method using the WorldToolKit C library. In the future, the "Viewer" will be definable by a Java 3-D graphics library, and then the simulation environment can be constructed as a Java applet. We are planning to implement a 3-D physical simulation environment in a shared virtual space.

Cross-age Tutoring as Cognitive Apprenticeship

Michiko Kayashima
Department of Education, Tamagawa University, Japan
kayasima@lit.tamagawa.ac.jp

Abstract: Collaborative learning, particular peer tutoring, involves learners in a process of inquiry through discussion or tutoring, and promotes inquiry and produces the effect of learning. The goal of this study is to verify this assumption. As an inquiry depends on what kind of question is generated, it is necessary to consider how learners generate productive questions. The approach taken in this study is to examine learners' inquiry in the aspect of question. The following analysis will show that the students' technique of inquiry is developed by the near tutors' suggestions. That is, cross-peer tutoring involves students in a process of inquiry through tutoring. The tutors aid this process by the "cognitive apprenticeship" approach.

1 Introduction

Learning theory has changed from "transferring knowledge" such as in a traditional education system to "having an interactive relationship with one's surrounding environments including others." In order to learn, learners have to think out what they do and then do it by themselves or through an interactive relationship with one's surrounding environment without instruction. Under this perspective, learning is a problem-centred inquiry by learners through social interaction. That is, a learner must have or develop the technique of inquiry.

There is an argument for the importance of making students inquire(Dewey, 1963). Students should develop the technique of inquiry. However it is difficult to promote learners inquiry because the technique of inquiry can only be developed by inquiring.

Recently the idea that peer interaction fosters learning has been widely accepted. Various kinds of practical studies have been examined, and many studies provide positive results of collaborative learning and peer-tutoring. However, much less attention has been given to when and why collaborative learning produces this positive effect.

Chan argued that effectual collaborative learning might be limited without the understanding of knowledge as problematic and as requiring explanation, and showed the efficacy of problem-centred inquiry in collaborative learning using a psychological experiment(Chan 1996.) Collaborative learning, particular peer tutoring, involves learners in a process of inquiry through discussion or tutoring, and the situation promotes inquiry and produces the effect of learning.

The goal of this study is to verify this assumption. As an inquiry depends on what kind of questions are generated, it is necessary to consider how learners generate productive questions. The approach taken in this study is to examine learners' inquiry and to find out what kind of questions are generated.

2 Peer-tutoring through computer network

We had to design a collaborative learning situation and record verbal interactions to find out the process of inquiry. For these two aims we designed a cross-age community through a computer network with intent to produce a peer-tutoring scenario.There is some research which shows that tutoring, especially cross-tutoring gives students the opportunity to learn activity through their own questions. Students ask more questions during tutoring than in classroom situations. We used BBS (Bulletin Board Services) under the computer network to help record all questions and answers during the peer-tutoring. The cross-age community consisted of junior students and senior students from different academic departments at different locations.

For the learning task, junior students, who were computer novices, learned basic computer concepts under the tutelage of senior students. Novices often have great difficulty mastering new domains. It is accepted that a better way to acquire a new domain is by tutoring.

3 Outline of the experimental curriculum

The course "Computer and Life" was presented to 34 junior colleges in 13 lessons (100 hours). The students in the department Art had no computer literacy and had no knowledge about HTML (HyperText Markup Language).

The 13 lessons were broken down as follows:

Lesson1: Students learn the basic computer operation functions.
Lesson 2-4: Students learn basic wordprocessing.
Lesson 5-13: Students learn HTML and create a Web Page.

Students were divided into nine groups consisting of an average of four students. Each group was assigned to two specific tasks. The first task was to research, using reference books and dictionaries, a new concept in computer science which is RAM(Random access Memory), ROM(Read-only Memory), and so on. The second task was to create a Web page to explain their interpretation of the new concepts. Requesting and engagement in explanation have been shown to play a central role in successful group learning performances.(Webb, et al. 1995, Miyake 1986, Chan 1996.)

In this way, unless students had much understanding of the concept in the first task, they were not able to use it effectively and efficiently in the second task. As mentioned earlier, there was the possibility that a student might need tutoring as they worked on their own. If that was the case, students could seek for assistance, using BBS, from senior students in the department of Engineering.

The easy-to-use BBS has a simple two-page structure. The dialogue is based on a simple strategy, starting with a question followed by a possible answer.

4 Kinds of interaction

The interacton in 8 lessons for two months was saved in the BBS. The analysis showed the questions' transition caused by the senior tutors.

At the beginning of the lessons for creating Web pages, the students were at a loss because of unknown concepts. Almost all students sent out vague questions on BBS such as "I do not know about a SCSI(Small Computer Systems Interface). Please teach me about it.". The first time when the seniors responded to a vague question, they provided a detail explanation. After they read many vague questions, they transferred their responses to "Before asking such questions, look it up for yourself." or "You should ask a question after first making it clear to yourself." They replied with suggestions based on their experiences. These suggestions had some effect as seen when some juniors then asked questions after first looking up the terminology in a dictionary or in a textbook, which were later discussed in the group. The vague questions were transformed into concrete questions.

In regard to concrete questions, the students asked for the confirmation of what he/she had interpreted and then the senior students provided a basic confirmation - either correctness or incorrectness. Some junior students presented examples to confirm their interpretation. For instance, "I suppose that all information is represented as one or zero. If so, is hiragana or katakana represented as one or zero?" Students who ask confirming questions tended to explain more accurately and in a more structured way than those who simply asked vague questions repeatedly.

With time, some senior students responded "You should inquire in detail" continued with a brief explanation. After this, the questions on BBS decreased.

5 Conclusion

The above mentioned analysis shows that the students' inquiry techniques were developed by the near tutors' suggestions. That is, cross-peer tutoring involved students in a process of inquiry through tutoring. The tutors suggestions were based on a "cognitive apprenticeship" approach. This involves modeling, coaching and fading. Advising what word to look up in a dictionary, helping them confirm their explanation, and then fading the help as they take on more responsibility.

Abstract

Recent efforts in manufacturing education have been aimed at developing more integrative and technology-based learning approaches which facilitate student teamwork. The Virtual Factory Teaching System (VFTS) addresses the educational needs of new and potential engineering students by creating a manufacturing education workspace that will exist in the intersection of the three domains of education, the Internet and virtual factories. The workspace takes advantage of advanced communication technologies in presenting manufacturing complexities to engineering, business, and other students interested in factory dynamics. It features a virtual factory teaching system (VFTS) accessible via the World Wide Web. University instructors will use this workspace to illustrate the concepts of factory management and design as applied in a realistic setting. The design of the workspace will enable students to participate in the functioning of the virtual factory by assuming the roles of various factory personnel in small team settings. Through acting out these roles, they will witness the range of decisions an engineer or a manager makes and their effect on the performance of a company. The VFTS will also be implemented in other educational venues, including K-12 schools in the Los Angeles area.

Background

The literature and research from the domains of education, the Internet, and virtual factories indicate the potential for developing a Virtual Factory Teaching System (VFTS). Numerous studies describe the usefulness of computer-based learning tools in classroom instruction. Various tools have been designed specifically for courses in engineering and the hard sciences. The manufacturing program places emphasis on information technology; for example, network teaching and research tools are being developed to study the complexity of supply chains.

The VFTS is designed not only to promote holistic understanding; but it should also facilitate student teamwork. Engineers and managers must learn how to function well on "virtual teams" that may span continents. Learning to work as a team member has additional pedagogical benefits for students beyond simply preparing them for future careers. It has been found that students working in collaborative groups have been better able to formulate concrete ideas and avoid misconceptions.

Virtual enterprises are considered key to re-configurable, computer-networked business structures that can find high-value, innovative solutions customized to customers needs. Corporations that use such concepts will require individuals who understand the complex dynamics of manufacturing processes. The VFTS will provide a platform for this training. The major benefit of a virtual factory is that physical system components (such as equipment and materials) as well as conceptual system components (e.g., process plans and equipment schedules) can be easily represented through the creation of virtual plant entities that emulate their structure and function. These entities can be added to or removed from the virtual plan as necessary with minimal impact on other system data. The software entities of the virtual plant have a high correspondence with real system components, thereby lending validity to simulations carried out in the virtual system meant to aid decision-makers in the real one.

The Project

This project addresses the educational needs of new and potential engineering students by creating a manufacturing education workspace that will exist in the intersection of the three domains of education, the Internet, and virtual factories. The workspace will take advantage of advanced communication technologies in presenting manufacturing complexities to engineering, business, and other students interested in factory dynamics. It will feature a virtual factory teaching system (VFTS) accessible via the World Wide Web. University instructors will be able to use this workspace to illustrate the concepts of factory management and design as applied in a realistic setting. The design of the workspace will enable students to participate in the functioning of the virtual factory by assuming the roles of various factory personnel in small team settings. Through acting out these roles, they will witness the range of decisions an engineer or a manager makes and their effect on the performance of a company. Student teams may even span institutional boundaries.

This project is divided into a series of evolutionary phases, beginning with the development of a baseline VFTS in the first year. The baseline VFTS will include all the major components that are deemed central to the theme of a virtual factory when used as an engineering education workspace. It will serve as a prototype for a full-scale model, which will be enhanced to address a broader range of student interests (e.g., with finance modules for use in business courses) as well as engineering needs (e.g., with capabilities for handling greater complexity and variety of manufacturing processes). The baseline VFTS will be implemented in engineering courses in the second phase. In the third phase, evaluations of the baseline VFTS will serve to drive system modifications. At this time, the VFTS will also be implemented in other educational venues, including K-12 schools in the Los Angeles area.

Our study proposes a creative solution to the problems posed in trying to physically replicate complex manufacturing environments by combining real site visits with virtual factory modeling and simulation. Opportunities unfold in the areas of inter-university collaboration that could span the country and the world, giving students valuable experience in long-distance collaboration on technical projects, while facilitating teaching and research efforts among students and faculty.

The Canadian Visual Arts Information Network Student Interactive Imaging Program

William Kirby
Centre for Contemporary Canadian Art
Canada
w.kirby@ccca.ca

Introduction

Cultural information can have significant added value when it is shared and re-used rather than being re-collected in different forms by various organizations. A central electronic source of reliable, up-to-date visual arts information reduces duplication and the need to collect and verify the same information more than once.

Canadian Visual Arts Information Network

The Centre for Contemporary Canadian Art (CCCA) was founded as a not-for-profit, charitable arts organization and operates as a flexible, accessible resource working for the benefit of artists, the arts community and the public at large. The CCCA seeks to excite the public about contemporary Canadian art by increasing their exposure to information about artists and their work, and believes that an integrated approach to information gathering and dissemination is the best method to achieve this objective.

The CCCA has set out to accomplish these goals by establishing *The Canadian Visual Arts Information Network (CCCAnet)* which is based on a national Visual Arts Database and Directory. The key to the database is in its comprehensive, reliable, up-to-date information about Canadian artists and their work.

Canadian Visual Arts Database and Directory

The Database is based on the *Multi MIMSY 2000* Information Management System developed by Willoughby Associates of Winnetka, Illinois. It already includes a Visual Arts Directory of over 2,000 entries (including more than 1,200 artists; over 400 public galleries and artist-run centres, art dealers, art consultants, and other visual art professionals and organizations). It also includes over 1,200 digitized works of art of more than 100 artists, and information on more than 100 contemporary art exhibitions and publications. More information and images of artists' work are regularly being added to the database as the material is received from artists.

The focus of the CCCA Database is on contemporary Canadian artists and their work. It contains detailed biographical information on individual artists; digitized images of their work in public, private and personal collections; bibliographic references; artists' statements; and will soon include audio and video clips of some of the artists speaking about and making their art.

Student Interactive Imaging Program

To build the database, the CCCA has initiated the *Student Interactive Imaging Program* by developing a partnership with Confederation High School in Nepean, Ontario. Under this program, students are involved in the digitization of 35mm slides from artists; galleries and other visual arts organizations; entering the images and related information into the CCCA Database; and in the design, construction and maintenance of CCCAnet.

Learning Benefits

As a learning activity, both the development and the use of the Canadian Visual Arts Information Network is a rich, multi-faceted environment that promotes many effective learning principles. CCCAnet has been designed to be an interactive learning web site that connects contemporary Canadian visual artists and their work to people throughout the world. In addition to publishing and promoting the artists' work the site is designed to allow students to interact with practising artists in order to enhance their involvement in, and understanding of, visual arts. This "expert/student" relationship is extremely important in the formation and development of understanding of the arts, but is often difficult to establish in schools. The evolving web technology makes this relationship possible.

Students who worked on the design and development of the web site not only acquired the knowledge and skills required for web page construction but also for the first time had a meaningful relationship with professional artists and their work. The knowledge that their expertise and work on this project would contribute to the appreciation of Canadian art around the world inspired the students to produce a quality product.

Dissemination

By compiling and making available a large, up-to-date bank of information, the CCCA seeks to give the visual arts a greater overall 'presence' by providing meaningful Canadian visual arts content to the arts community, universities, schools and libraries, and to the general public across Canada and abroad over the CCCAnet web site <http://www.ccca.ca>.

Canada's SchoolNet

The CCCA is working with SchoolNet to help disseminate CCCAnet to schools across the country. *SchoolNet* is a federal initiative in collaboration with provincial/territorial ministries of education to help connect all 16,500 schools (including all 417 First Nations schools under federal jurisdiction), and 3,400 public libraries across Canada to the Information Highway. *SchoolNet Digital Collections* is an innovative Industry Canada program designed to give Canadians 15 to 30 years of age entreprenurial and technology-based job experience converting collections of material into digital form for display on SchoolNet. Teams of young people work with businesses, institutions and other organizations to make a wealth of largely undiscovered Canadian material accessible on the Information Highway. This program has assisted the CCCA in engaging students to develop CCCAnet.

Distance Learning

The Centre for Contemporary Canadian Art is also working with the Ottawa-Carleton Research Institute (OCRI) and U.ACT Incorporated of Gloucester, Ontario, to develop further interactive methods of disseminating cultural information from the Canadian Visual Arts Information Network across Canada and around the world. The CCCA is currently experimenting with interactive software designed and developed at the Multimedia Communications Research Laboratory (MCRLab) at the University of Ottawa. JETS is a Java-enabled 'TeleCollaboration System' designed for the real-time sharing of Java applets. Using any Java-enabled Web browser, multiple users in a telecollaboration session are able to share generic applications in the form of Java applets

Conclusion

The learning environment provided by the Canadian Visual Arts Information Network and the Student Interactive Imaging Program is dynamic and continually evolving as new works and text are added to the database and as additional interaction takes place. It represents a learning opportunity that can be revisited many times. By using the tools of technology to facilitate student/artist dialogue, therefore, it is hoped that more youth will become actively engaged in the visual arts in a variety of ways.

Abstract: This presentation outlines a structured course development and delivery strategy in development aimed at facilitating a learning environment that can be delivered in a variety of delivery formats. This strategy aims at breaking away from linear course development models towards a dynamic, ongoing, group-oriented model through the use of Standard Generalized Markup Language (SGML). Insights into the process of prototyping such a strategy in the context of developing a high school Information Technology course will be offered.

One of the core challenges for those who aim to support distance education is that of creating curriculum-relevant learning environments that facilitate engaged learning. Another is the need to be able to meet a set of learning outcomes using multiple modes of delivery and interaction. These challenges can be met with an approach that balances the need for structured content management with the immersion of the learner in the material.

This presentation describes a structured course development and delivery strategy aimed at facilitating a mediated, collaborative learning environment that can be delivered in a variety of formats: on the Internet, in print, on CD-ROM. The outcome of the process is a set of structured content modules that exist *independent of output format*, but which can be easily moved into particular delivery media on demand. Considering output format separately means an audience of students can approach and interact with course materials in ways appropriate to their specific needs.

At the core of this strategy is SGML *(Standard Generalized Markup Language)*, an ISO standard for describing structured content. Anyone who has authored WWW pages is familiar with at least the face of SGML; HTML *(HyperText Markup Language)* is a specific *document type* instance of SGML. However, whereas HTML has evolved into a sort of online typesetting language, the larger sphere of SGML offers powerful and flexible options for describing electronic documents according to their content-inherent attributes.

Such a system ultimately allows for group authoring, easy updating, rapid re-purposing, and publication of materials to multiple delivery media. Format, presentation, and interface become *a function of* the structure of the content, rather than defining it. The goal in development is to produce and organize multi-dimensional content and to be able to facilitate its delivery in an ongoing fashion.

The course development process revolves around the creation and maintenance of a central set of structured (marked-up) documents in a clean, non-output-specific form which can thus be easily accessed, edited, revised, and worked on by a team of course authors, instructional designers, delivery specialists, teachers, and facilitators. Our aim is to break away from linear, discrete course development and revision models and to embrace a groupware strategy that keeps material alive and current through development and delivery.

At the writing stage, course materials will have relatively little structure; the material is written either as plain text or styled word processor documents. The next stage of the process sees the content evolve into a highly structured "clean implementation" phase. Here, content is encoded and arranged in a highly defined file structure, using *Adobe FrameMaker+SGML* as a core development engine. At this point, decisions about publication options can be made. These include not only not delivery format decisions (Web, print, or other), but also course delivery considerations such as mediation, access, and other logistics of instructional design.

The course material itself takes the form of "short-branching hypertext," which is multi-dimensional and polyvocal while remaining generally linear. On screen, sub-topics, time-sensitive material, and other perspectives pop up in subwindows or are set into existing pages without taking away from the central linear thread. In print, subtopics occupy traditional layout devices such as sidebars, pull-quotes, and footnotes. The finished product presents a number of voices and points of view in a single visual field.

Further to this is an idea we hold in high esteem: that a course—whether delivered electronically or in print—exists in a larger context, drawing upon larger themes, dialogues, and threads. We feel that a structured development and delivery environment can include or at least facilitate links to the a variety of hypermedia forms, be they external texts, interactive pieces, conferencing and discussion areas, or other, yet-to-be-realized media. By developing in a structured way it becomes possible to embrace a standard scheme for referring to external elements.

We hope also to be able to share this strategy and model with other courseware developers. This project is very much based on open systems and simple, non-proprietary tools. We are interested in developing successful strategies rather than "solutions".

The process is being prototyped as the development and delivery model for the *Information Technology 11* course offered this year by the Open Learning Agency's New Directions in Distance Learning (NDDL) program.

The Open Learning Agency is a public non-profit agency specializing in the delivery of distance education and training through the innovative use of a variety of technologies. The OLA is funded by the Government of British Columbia and by grants, tuition fees, sales, donations, sponsorships, and partnerships. It is headquartered in Burnaby, British Columbia, Canada.

A Web-based Framework for the Complete Integration of Teaching Concepts and Media in Computer Graphics Education

Reinhard Klein, L. Miguel Encarnação
University of Tübingen, Wilhelm-Schickard-Institute for Computer Science
Interactive Graphics Systems Lab (WSI/GRIS)
{Reinhard.Klein, Miguel.Encarnacao}@Uni-Tuebingen.DE, http://www.gris.uni-tuebingen.de

Abstract: Topics within computer graphics still cannot be adequately presented and explored with traditional teaching methodologies and tools. An integrative approach to combine lectures, examples, programming exercises, documentation etc. is greatly needed, this supported by a common sophisticated interface.

At our Lab we developed a computer graphics course that focuses on this need. The practical part of the course consists of Java-based example programs and exercises on the computer in which the students can test the theoretical concepts and generate their own experiences.

The integration of the different theoretical and practical parts of the course is realized through a common Web-based interface to the system. The main objective is to support the students in gaining an insight into the research methods and experimentation processes that occur in the development of new graphics techniques.

(*Note:* A more detailed version of this short paper can be found in the corresponding ED-MEDIA'97 CD-ROM Proceedings.)

Introduction

The topics *visualization* and *interaction* belong to the major parts of the area of Computer Graphics. Nevertheless, these issues cannot be adequately presented for educational purposes solely with traditional teaching methodologies and tools, such as blackboards, slides, and even videos. The general problem seems to be that the students do not gain any insight into the research methods and experimentation that actually occur in the development of new graphics techniques. Such an insight can only be provided through the incorporation of experimental methodologies into computer graphics courses.

Nowadays, Java provides an excellent software platform to solve the problems mentioned above through its platform-independency and the support of shared and distributed objects that provide the means to allow students to collaborate with each other and their tutors and to complete and explore the programming exercises at home (on their PC's).

The Course

The first experiences were collected throughout two consecutive computer graphics courses which contain the basic parts of computer graphics. The courses have been tailored to students of computer science and contain a variety of programming assignments. In its current form the courses are not well suited e.g. for engineering students: Such students prefer a course where they can learn how to use commercially available packages instead of having to invest too much time in programming examples of basic computer graphics algorithms.

The course contains the following topics: Computer graphics hardware, raster algorithms with aliasing and anti-aliasing, 3D-transformations, visibility, color, local illumination schemes, modeling techniques, simple animation, texture mapping, global illumination techniques (ray-tracing, radiosity), and volume visualization.

The programming exercises are done in groups of two or three students using the Java-based programming environment. The Java source code of the environment is available on a ftp-server for different platforms and can be downloaded by the students. A comprehensive written instruction is available for each exercise in the form of HTML-pages. For each programming exercise, a small example program for which the source code can be downloaded as well gives a short introduction into the topic. The exercise itself is widely pre-programmed; the students have to fill-in the parts that are left blank for the assignment. The source code of the exercises is also accessible through the Web, thus allowing for permanent switching between the theoretical background information, the description of the exercises, and the source code of the latter. The aim is to support the students during the completion of their programming tasks.

Via hyperlinks to parts of the script in postscript format, the students can review the theoretical background for every single exercise.

The Java-based Programming and Experimentation Environment

The programming environment is the crucial part of our concept, since it is the basis for examples as well as for the programming exercises.

The new generation of 3D software tools is *object-based* and such tools are composed of extensible sets of 3D objects, objects for interaction purposes, objects for transformations, objects which represent materials, etc. Therefore, we integrated object-oriented ideas into our system as used in these packages. This way our students get familiar with the concepts of modern graphics systems and up-to-date object-oriented graphics programming through the usage of our system.

Object-oriented programming is also suitable to provide the user with a set of basic objects. Geometrical objects like points, lines, etc. are implemented as own classes with own methods and can be re-used for different applications.

As mentioned above, the documentation in form of Web-based hypermedia information allows for repeated switching between the theoretical background information, the description of the exercises, the source code of the latter, and more, thus supporting the students during the completion of their programming tasks. In addition, the understanding of class hierarchies can be tremendously increased through nested hypermedia documentation.

Conclusions and Future Work

The Java-based version of the programming environment [WSI/GRIS, 1996/97] has been applied to two consecutive semesters of the computer graphics course held at our department in 1996/97; an earlier version to two consecutive semesters in 1995/96 [1].

Independently from the evaluation of questionnaires that were handed out, we were able to discover some remarkable effects of our course: In comparison with courses held in earlier years and covering the same topics of computer graphics, less students quit after successfully completing the first course and did not participate in the second (20 % in 1996/97 and 30 % in 1995/96 compared to 45 % in 1994/95 and 50 % in 1993/94). From the students that successfully completed the second course, many more were immediately involved in current projects at the Lab in form of programming activities such as practical courses and B.Sc. and M.Sc. theses (30 % in 1996/97 compared to 20 % in 1995 and 20 % in 1994). We noticed that several students started to add non-requested features and functionalities to the system after having gotten familiar with it.

Future work includes the integration of VRML2.0 to allow for the realization and use of more complex scenes and for the support of collaborativeIn order to serve with our course a larger, inhomogeneous community of people interested in computer graphics, future research has to face questions of adaptive user-interfaces based on first experiences and promising results made in our group in this area.

USING VIDEOVOICE IN A PRONUNCIATION COURSE IN FRENCH AS A SECOND LANGUAGE

Hélène Knoerr
Institut des langues secondes, Université d'Ottawa, Canada
hknoerr@uottawa.ca

Abstract: The multimedia technology is now well established in most classrooms and language labs all over North America, creating a new world of possibilities for teachers of pronunciation in French as a second language since it brings resources that were previously unavailable to the language classroom. Now that advanced speech recognition systems are no longer restricted to research facilities and are commonly and more affordably available commercially, they bring with them new tools to help the second language learner hear and pronounce phonetic and phonological features. This speech communication is about one of these new tools, VideoVoice, developped by Micro Video, and about how it can be put to use in a pronunciation course in French as a second language.

VIDEOVOICE

VideoVoice was developped by Micro Video as an aid in speech therapy. It is designed to be used in a face-to-face situation by therapists to help young children with various pathological problems. It is quite innovative in that it allows the user to have a visual feedback of his utterances, be they isolated sounds or entire phrases, via an easy-to-read visual display. The system also allows for immediate comparison between a model utterance and its imitation [Fig.1]. Another interesting features of VideoVoice is the extensive use of video arcade style games.

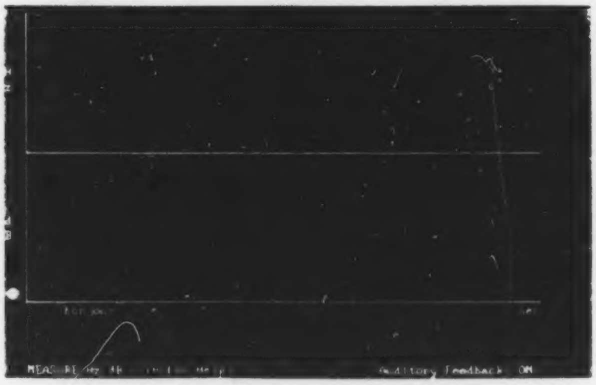

Figure 1: visual display created by VideoVoice

BEST COPY AVAILABLE

ADAPTING VIDEOVOICE TO A LANGUAGE CLASSROOM SITUATION

I have been experimenting with VideoVoice in my pronunciation course since January. I have chosen to use it as a tool to teach and learn intonation patterns (pitch), because it offers different ways to display intonation patterns. The Temporal Display shows model patterns as well as students' trials on a full or split screen, with the same time frame. There are also a number of games which can be used to encourage practice. For example, Pitch Painting: a varied pitch will paint the screen a wide range of different colours, whereas a flat intonation will paint the screen one or two colours only [Fig. 2]. With Hickory Dickory Clock, another pitch- oriented game, the student's rising or falling pitch makes the mouse run up or down the tower.

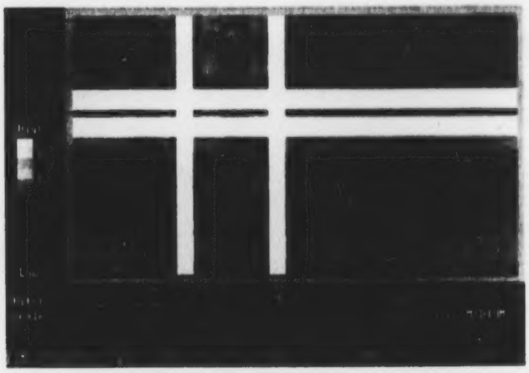

Figure 2: a varied pitch will paint the screen a wide range of different colours

I have designed a VideoVoice-based learning program for my students. Since VideoVoice has an Assessment/ Report Menu, keeping track of the students' progress should be an easy task. The computer will keep track of the number of trials and the scores for each model, and give a detailed report on the student's progress from session to session. I will be able to report on the students'progress shortly.

FACING THE TECHNICAL CHALLENGES

VideoVoice was designed to be used in a face-to-face situation by therapists to help young children with various pathological problems. Adjusting the program to a language learning context brings about a series of challenges. First of all, VideoVoice was not designed to be networked: a card must be installed in the computer hard drive, and it cannot be shared. Likewise, a filter box has to be plugged into the computer, and cannot be shared either. Buying more than one program is a costly option: the complete VideoVoice package sells for 3 000 US$. Consequently, the computer on which VideoVoice is installed must either be a stand-alone computer or be set apart from the network via a special program to be designed by the network technician. Minor network-related annoyances are the default labels (Patient, Therapist, Clinic) which cannot be permanently changed to the other available labels (Student, Teacher, University). Also, with a network, nothing can be stored on the hard drive. As a result, students have to work from individual floppies, which limits the quantity of material that can be stored and affects the speed at which models are retrieved.

Other problems are: the keyboard: the default layout being US keyboard, it is therefore impossible to have all those funny little things that are essential to French -accents, cedillas, and tremas; the system does not support laser printers; some sound cards are not supported either. However, despite all this, using VideoVoice in the French language classroom does benefit the students, as the first results of my experiment seem to indicate.

"Do Computers Belong in a Museum?"
Providing Public Access to Information Technology in a Museum. An Australian Perspective.

By Allan Kreuiter MSc (Sci Comm) Powerhouse Museum, Australia

Abstract Programs and exhibitions at the Powerhouse Museum of Applied Arts and Sciences (MAAS) have demonstrated by the response that they generate that there is a strong interest in Information Technology in Australia. Schools also have indicated that recent proposals to put an internet access in every school in the state and the
fact that we have the second highest relative use of the internet after the USA mean that they a strong interest in doing programs in IT as part of an integrated visit to a museum.

The focus of this paper is that a museum based access for IT must address these two areas of IT and museum culture, in order to create programs that fulfil the needs of its audience to enlightenment and demystifying of the negatives and positives of Information Technology.

Is there a role for museums in educating and giving access to the public within a Museum? The Powerhouse responds to these needs by developing a specific area called the ITC (for Information Technology Centre).The ITC works with both education and public groups to foster public awareness of and access to IT. It does this by using cutting edge educational software and commercial IT applications as part of divers styles of visits integrated with MAAS museum access.

Of particular interest has been the development of visit packages specifically for design and fashion groups to interact with recent software developments and combine with museum displays of designers work. This integration with museums and material culture has also been successful in fields such as history of computers, language use training and creative writing.

Have they succeeded or have they simply created a Computer "pocket" isolated from museum activities that does not fully integrate with the exhibitions or address the real needs of the general public nor museum visitor.

I want you to imagine the computer that is on your desk at home, or beside you now. Is it the same computer as the one you were using last year? How about 5 years ago? Did you even own a computer 10 years ago? How different is the software you use and the way that you use it. This is the dilemma that faces museums using and displaying IT today.
Computers are so much a fabric of our visitor's existence that as well as showing the history of computer technology museums must respond to current developments to reflect both society and future changes that will strongly influence the lives of our clientele. This must show the possibilities inherent in such technology as well as its positives and negatives
Is this possible and how can it be done?

Interest in Science and Technology

Before continuing with this idea I should deal with the assumption that there is a need for such education about computers. Is there an interest and how is it expressed?. Leaving aside such anecdotal evidence as the response of our visitors, there are three chief indicators that there is an interest: Internet connections, attendance at shows and surveys.
Australia has the second highest rate of internet connection per household; whether or not this interest will continue to grow or not is another matter but it certainly demonstrates significant trends in interest. Computer shows and expo's have vast audiences, and if we add in the computer games market this is expands even more. Thirdly a survey of American households (SCIENCE & ENGINEERING INDICATORS - 1996) states that 40 % of all surveyed expressed a high interest in science discoveries and the use of new technologies, while only 10% thought that they were actually well informed about such issues)
Finally all the schools in our State have plans to be connected to the internet by the end of 1997, since education groups are a major market of ours this is almost sufficient reason on its own.

Powerhouse Solutions

The Powerhouse Museum responded to this need in a number of ways, first it created an exhibition of computers from Babbage to IBM. Next it built the Information Technology Centre to create a place for growing vibrant computers in a museum.
The first is a case of a static museum display that reflects museum culture. It covers important areas for students and visitors like the history of computers and simple demonstrations. But there is a limit to the amount of exposure to Information Technology that can happen, as the average visitor looks at an exhibit for less that 10 seconds.
A solution that may prove to be the most effective use of computers in a museum is the creation of an area dedicated to computer power that can be accessed by the visitor with the aid of fascilitators, the Information Technology Centre. In many cases computers are too limited in their flexibility to the general public. Thus education on their possibilities is

limited to either demonstrations, which are disappointing to most, or to the expertise already existing within the visitor. The ITC answers this gap by planning education groups with cutting edge software, or general visitors with a short training and exposure to newer developments. Thus general visitors with no experience but great interest in the Internet would be shown the software and with a fast link and computers be led through some simple tasks to expose them to the possibilities of the medium.

Alternatively a design group may visit the ITC and be trained in the use of a specific set of tools and then guided though a design brief related to their study. They could use CAD principles to design a chess piece and cut it out on a CAM lathe, or use digital camera and manipulate images, and then create a poster based on inspiration received in a visit to the another exhibition within the museum whether it be IT or fashion or visual art.

The ITC however works with both education and public groups to foster public awareness of and access to IT. It does this by using cutting edge educational software and commercial IT applications as part of divers styles of visits integrated with MAAS museum access. What this means is general visitors are exposed to new software that shows the importance and relevance of it to their life, and education groups are connected with the curriculum to allow teachers to justify visits doing this sort of education based activity and to use it in future work in their classroom.

Two other innovations increase the value of this centre. Pre and post visit events especially ones found on the web site have been shown to greatly enhance the understanding and enjoyment of visitor groups[Follette RL 1987] . These do not have to be computer related to add value to the visit eg the design of a dress on paper by a class with allow them to understand the advantages (and limitations) of doing so on a computer. The second innovation is the concept of connection to exhibitions. Use of an exhibition combined with use of the ITC establishes a connection between the two, a connection that can easily become a divide between a computer centre and the museum it is based within.

Community Interaction

The sort activities based in an ITC can be seen to be strongly empowering community groups in IT, thus allowing the museum to reach much more of the public than would normally be approached. For example the ITC runs events for unemployed youth group which are a combination of training and phobia reduction for these disadvantages groups. It does not attempt to replace structured training but it may allow the visitors to approach such training without disadvantage, or at least show them some future possibilities in their lives. Other ideas include encouraging retired groups to visit in a thing called Cybersurfing for beginners using a promise of fast links, cheap rates and above all personal interaction. It has been found that this certainty of having a keen knowledgeable source able to respond to questions constantly present was an antidote to the "impersonal intimidations" of Information Technology.

Criteria for a working Computer space

Computer demonstrations are most successful when they follow the Socretean Principle " What I hear I forget, what I see I remember, What I do I understand" To promote understanding in visitors computers have to be interactive in a meaningful way. Partly so the possibilities of the system are remembered, and partly to empower and encourage visitors to tackle the questions and implications of a computer literate society. A danger is also that the interactives become toys and this is where a constant reference to museum culture and the social implications of IT is important to emphasise.

You need tools that show the possibilities of the future that can be used today, good examples are digital cameras and interactive telescopes. At the same time the envelope must be pushed to show future possibilities, things like 3D simulations and Waldo remote applications or running an on line telescope have great potential to excite people in asking questions and having interactions with IT.

Have we succeeded?

Have they succeeded or have they simply created a Computer "pocket" isolated from museum activities that does not fully integrate with the exhibitions or address the real needs of the general public nor museum visitor. Our interest levels remain high, we were booked out last year and are getting so again, and the response from teachers and students has been enthusiastic. The isolation will always be there in part, computers have to have some cages for security and some conditions for their care and feeding, but the computer "petting zoo" should encourage all visitors to loose their fear of the dangerous beasts, and maybe allow others to see their fragile beauty in a new light.

This is the question that will have to be answered by both time and by the responses of our visitors, perhaps we shall only know when in a year our inspired visitors return, or in 20 years when a computer literate generation brings its next generation to visit the ITC.

LEGO-Logic: Developing Scientific and Technology Thinking

Dr. Nira Krumholtz

IDEA Center - Dept. of Education in Technology & Science
Technion - Israel Institute of Technology
Israel
E-mail: ttrnira@techunix.technion.ac.il

Abstract: LEGO-Logic is a learning environment developed to integrate creative construction of concrete machines and models with an introduction to computerized processes control. LEGO-Logic was developed at the IDEA[1] Center, to facilitate the learning of both scientific concepts and their technological applications. Through the suggested type of learning the student not only learns about science, but also practices science. In this way, he or she learns, not only abstract scientific and technological principles, but about scientific and technology processes as well. With appropriate guidance and direction, the LEGO-Logic environment enables the learners to build their knowledge through varied, rich experience.

The qualification of learners to live in a technological world, will be evident in their ability to efficiently utilize technology, use existing technology to plan and manufacture new products, and think of directions to develop new technologies. Thus, learning technology has to involve two main activities: using technology and developing new technologies. Understanding the nature of technology and its influence on human life is essential for the development of curriculum for Technology and Science Education.

Curriculum Development Based on the "Spiral Model"

In order to study the interrelations between technology and human beings and to realize its influence on the development of society, a theoretical model called "The Spiral Model of Technology Evolution", was used (Krumholtz, 96; 97). The "Spiral Model" describes the interrelations among four factors: human needs, physical phenomena, technological constraints and technological solutions.

We suggest an educational approach for teaching science and technology that allows the learner to experience technological activities and technological processes. A technological process includes the identification and separation of all four factors in the "Spiral Model". The learning experience in a technological process starts with identifying a problem - an human need - and ends with raising, choosing and producing a solution - a practical product. Science and technology learning is inherent to the overall learning process when the learner tries to deal with technological problems and to overcome physical constrains.

The Learning Environment

In order to give the learner the opportunity to go through a process similar to the process of developing a technological product in real life, we have to choose a simulation system suitable to the learner. That is, it has to be easy to use, close to the content of the child's world of interest and suited to his or her level of development. Moreover, in order to teach scientific and technological concepts and principles in a way that will lead the learner from intuitive understanding of the concepts to a more formal, scientific understanding, it is necessary to provide the learner with a wide range of concrete experiences using simple models and familiar tools.

We found that LEGO DACTA computer control systems: LEGO-Logo and the later development ControLab, meets these requirements. They can be used in classes as "Micro-Worlds" that the kids can operate in (Resnick, 1993). We developed learning activities that allow the learners to experience technological processes and physical phenomena. Through the activities learners gain practical experience in planning, constructing and operating physical models that are computer controlled. The learners are building models from LEGO bricks, including motors, lights and sensors and using the computer to control the operation of the models. Such models are for example, traffic-lights that simulate real operation, greenhouses that open and close doors according to the temperature inside the greenhouse, remote controlled wheelchairs, washing machines, conveyer belts that identify boxes according to size or color, elevators, racing cars, etc.

The Learning Process

Following the five stages of development of technological products, we suggest that the children go through five stages in the learning process and become both users and developers of technology:

1. Learn about human needs - identify one need or demand.
2. Plan and design a solution - suggest a LEGO model that will provide an answer to this need.
3. Carry out the plan - build the LEGO model and program the computer to control the model's operation.
4. Market the product - exhibit the product in the classroom.
5. Suggest future developments - for your LEGO model to respond to new demands it may trigger.

Advantages and Difficulties

The LEGO-Logo learning environment was used with various groups of learners, both school children aged 9 to 15 and teachers of elementary and junior high school. Based on our experience we found that:
LEGO Models - the LEGO DACTA computer controlled models answer our needs for a simulation system which can help deal with the technological world. We realized that the LEGO bricks and the variety of products, allow us to choose different models for the different populations. The great variety of LEGO models and building elements, made it possible to define an evolving line of models with increasing levels of complexity.

Control Software - Working with the programming software TC-Logo and later with the ControLab software, we identified some basic difficulties:

1. It takes time to master a formal computer language, in this case the Logo language.
2. For young and novice learners the programming language is too complex, even without considering time limit.
3. Israeli children are not familiar with the English language and this poses the greatest obstacle for young learners.

We realized the need to have a programming software that:

- Keeps the powerful ideas of Logo programming, such as structured programming, simple recursion, closed-loop and open-loop control.
- Is easy-to-use in relation to the ability of the user.
- Is user friendly, for example, contains commands which are represented as icons and not as words.
- Has on line detailed help screens, to allow inquiry and self learning.
- Does not require any previous experience in computers.

We defined the concept for a programming software that in cooperation with a software-firm in Israel was developed under the name of *TechnoLogica* (TechnoLogica, 95).

LEGO-Logic - The New Learning Environment

TechnoLogica software, the LEGO models and the learning activities and processes based on our educational approach, composed a new learning environment called *"LEGO-Logic"*. For the teaching of technology we chose to emphasize the role of the logic of the control structures, defined by using *TechnoLogica*, rather than programming based on formal computer language. Therefore, *TechnoLogica* was developed as an icon based software that permits the user to define various control structures (IF, IF-ELSE, WAITUNTIL, REPEAT) without the need to use any formal programming language.
TechnoLogica allows three modes of control:

1. Immediate mode of *manual control*.
2. *Automatic Control*: Open-loop control, executing a list of commands.
3. *Feedback Control*: Closed-loop control, using sensors for feedback.

To let the learners experience an instance of technological evolution, the models are first operated manually. Then, a motor and batteries are added to operate the model by electricity. At these stages the learner operates the models in on/off operations, under manual control.

At a more advanced stage, the model is connected to a computer and is automatically operated, controlled by *TechnoLogica* procedures, programmed by the learner. In the final stage, sensors are used to enable feedback in the control loop.

In the final exhibition, which is part of the marketing phase, each participant raises suggestions for further development of the product, that may satisfy new needs that will be triggered through the use of their model.

The more advanced stage is when the motor is used and a procedure is programmed to operate the model. This operation is called an open-loop control or an *automatic* operation.

In the last stage a light sensor is attached to the elevator and it allows for *feedback* control, when the light sensor "sees" each floor and the computer "tells" the motor to wait for 3 seconds, before going on to the next floor.

The future developments for this elevator model, that are suggested by the learner, are based on the need for safety that arises when the elevator is used. Another light sensor could be used to "see" if there are people standing in the way to prevent the movement of the elevator door. Another possible development consists in the elevator "seeing" if there are at all people who actually want to stop in each floor.

Research Results

LEGO-Logo and LEGO-Logic were tested with different groups of learners of different ages and with different needs: average learners aged 8 to 14 in a special research setting and in normal class settings; gifted kids aged 6-8 and 13-14; learners at the age of 12-14 with learning difficulties

One of the studies engaged three groups of 7th and 8th grade learners that went through the process of developing a technological product according to the learning process that was described above (Krumholtz, et al., 93). The analysis shows that physical concepts such as, speed, acceleration, static and dynamic friction, gravity, force and balance were involved and that most learners (87%) had reached intuitive understanding of the concepts. Some of the learners (24%) expressed more formal scientific understanding of the concepts.

The study that had been conducted with learners with learning difficulties, revealed that the learners had reached an intuitive understanding of the above mentioned technology phenomena, to some extent (Krumholtz and Zodik, 1993). What was most significant in their experience, as was expressed by them at the end of the learning period, was the chance they had been given to create something of their own - a solution which they invented. Their expressions of creativity ranged from merely inventing a name to a given model, to suggesting various new operations to its function, and for some of them to building their own mechanical model.

An Evaluation of a Web-Based Distributed Learning Environment for Higher Education

Dr. Robert LaRose, Telecommunication Department, Michigan State University, USA, larose@tc.msu.edu

Jennifer Gregg, Telecommunication Department, Michigan State University, USA,
greggjen@pilot.msu.edu

Dr. Carrie Heeter, Telecommunication Department, Michigan State University, USA, heeter@msu.edu

Abstract: The multimedia model employed in this project is an attempt to produce cost-effective instruction for the world-wide web by building upon audio and visual material captured in the classroom. This research compared the effectiveness of a multimedia Web course with conventional classroom learning under a controlled experimental design and found no difference in student performance.

Course Design

An introductory course in MSU's Telecommunication Department, TC100 Introduction to the Information Society, is the focus of the research. It uses Straubhaar and LaRose (1997) as its basic text. The course was previously delivered on campus in lecture halls with 100 to 300 students. A set of Web pages were created from lecture outlines in the textbook's Instructor's Manual. Links to Web sites that provided appropriate visual aids were added. The Web pages and the links were presented live in the on-campus lecture course during fall term, 1996. Small groups of students sat at the front of each class and responded to questions posed by the instructor. Thus, the give and take of a small classroom setting was adapted to a large lecture course. The classroom audio was recorded.

A Web site featuring the same course outlines, web links and review quizzes seen by students in class was designed by MSU's Communication Technology Laboratory. The classroom audio was linked to the appropriate pages on the course outline which the user controlled with a Real Audio player. The external links were automatically launched at the appropriate points. In short, the interface amounted to a "talking course outline" which faithfully captured the original classroom interactions.

Procedure

The completed web pages were posted on MSU's Web server with password protection so that only students enrolled in "virtual TC100" for spring term 1997 could view them. Students for "virtual TC100" were randomly selected at the start of the term from a pool of volunteers from two on-campus lecture sections of TC100. Students not selected to participate in the "virtual" course were the control group and continued in their on-campus lecture sections, where the same web pages and links shown in class the previous semester were once again used by the instructors on campus. Students accessed the pages through public computer labs or personal computers in their residences.

BEST COPY AVAILABLE

Student progress was monitored via student log-ins and by having learners submit written answers to review quizzes on a regular basis. Email accounts and chat rooms were provided to facilitate communication with the instructor and to distribute course-related announcements. Samples of the course materials may be found at http://www.msu.edu/virtualu/tc100.

Results

For this preliminary report, the grades on the first examination were compared between the experimental (web course) and the control (classroom) groups. The exam consisted of seventy-five four-choice, multiple choice items. It was administered to both groups on printed paper forms, although the experimental group entered their answers into a web form while control students used conventional mark-sensing sheets in their classrooms.

The experimental group had a slightly higher mean score (**x**=54.66, sd=9.52) than the control group (**x**=53.2, sd=8.68) although the two means were not significantly different (t=.46, p=>.05).

Discussion

Thus, we conclude that "virtual TC100" is equally as effective as the classroom version. As of the first examination we did not confirm Schutte's (1997) finding that web courses are *more* effective than their classroom counterparts, although our data did show a tendency in that direction. However, it is important to note that the results of the initial exam may reflect the difficulty many of the virtual (experimental) students had in accessing the web materials and navigating through them. On-campus labs were not made readily available as had been promised, and a number of students apparently failed to realize that they needed to click on "next" to reach subsequent pages in each lecture. Thus, the experimental group may very well exceed the control group after all the results are in.

Implications

This course could serve as a model for Web course preparation which captures the sights and sounds of real classroom interaction with minimal additional effort and expense, at least once the initial delivery platform is created. As such, it raises the possibility of creating multimedia Web courses within the parameters of conventional teaching and teaching assistant assignments. The same multimedia "shell" will be adapted to other courses, taught by other instructors, simply by recording classroom audio and posting Web page versions of overhead transparencies. Unlike Schutte (1997) the course does not have to be consumed in "real time" and can be re-used over several semesters. This could radically alter the economics of multimedia course preparation, putting them within the ken of all instructors, not just multimedia specialists, and make it possible to offer small-scale courses as well as large ones, realizing the ideal of a "Web major."

On-line Interactive Educational Multimedia via Residential Broadband Wireless Access

Bill Lavery and Tony Cricenti,
School of Biophysical Sciences & Electrical Engineering
Swinburne University of Technology, Australia
Email: wjl@swin.edu.au and tcricenti@swin.edu.au

Abstract: Internet delivered on-line multimedia education is likely to develop into a major mechanism for the provision of off-campus education. It is envisaged that students will access on-line educational services via a broadband internet network accessible from the home. We describe network architectural models for such a scenario, and propose a 'study process' model appropriate for on-line multimedia education. We then consider issues of the resulting data traffic in the links to the clients, for this link is typically the bottleneck. Assuming that wireless access will be cost effective and provide desired mobility, we examine the impact on the educational process in which this access to the home is via broadband wireless taps into a broadband fibre / cable network.

1. Introduction

In on-line education, a student uses a personal computer to access an educational server computer, the latter typically located at a university. The student learns by working through the material downloaded from the university computer, interacting with educational software executing on the student's PC, experiencing information presentation, simulations, tutorials, and tests (formative and possibly summative). Examples of tomorrow's On-line Multimedia Education (OLME) can be found in today's high quality educational CDs (eg [Ryan 97]), for student exposure to the latter will set the market expectations [Sykes & Sewell 96].

In this paper we examine some of the issues involved in how the finite capacities of telecommunications networks will impinge on such internet delivered on-line multimedia education.

2.0. Internet Delivered On-line Multimedia Education

We consider the scenario in which students work at home, accessing their on-line courseware via a broadband network as in Figure 1.

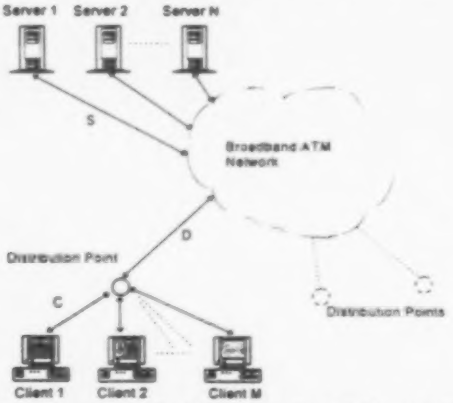

Figure 1. Architecture of Residential On-line Multimedia Education.

Students (1...M) work at personal computers, learning by executing OLME software (the courseware), which has been downloaded from the OLME servers, 1 ... N. Students obtain rights of access (passwords) to the courseware by enrolling in courses / subjects.

BEST COPY AVAILABLE

The S and D links of Figure 1 will typically be provided on high capacity Asynchronous Transfer Mode (ATM) fibre networks, which are economic in such highly shared links. The C links however serve only one client, and so will normally not be fibre, due to cost considerations. Thus the C links will typically be of limited capacity and may involve shared media with a joint capacity limit, eg as in broadband wireless [Celidonio & Di-Zenobio 96] or hybrid fibre coax trees [Sykes & Sewell 96]. The capacity limitations of the C links, and the characteristics of ATM networks at high traffic loads, must therefore be considered in the design of OLME for such internet delivery. In addition to the OLME traffic, and not shown in Figure 1, are all the other services that the ATM network will also be conveying. Thus, as well as the OLME traffic, there will be various multi-service, multimedia, multi-client traffic flowing through the ATM network, and the latter will sometimes impact on the OLME services, and vice versa.

'Doing a subject' consists of working through a number of 'Modules' and each such module consists of a number of 'Interactive Screens'. Thus we model the data transmission involved in such internet delivered OLME as bursts, described in three levels of timing diagram (see figure on CDROM), involving 'Download Data Bursts', 'Lessons', and 'Study Sittings'. The *Download Data Bursts (DDBs)* are short bursts of data which are sent to the client, corresponding to one (usually) interactive screen, which the student then interacts with to learn. The *Lessons* are periods over which the student learns a topic by interacting with a series of interactive screens, where each screen is downloaded when the student requires it, in the sequence specified by the student and/or the supervisory software; thus multiple DDBs constitute one lesson. A *Study Sitting* is the period of time that a student spends 'connected' to a server, before switching off the computer or disconnecting the communications link.

3. Transmission Considerations

The Client (C) links in Figure 1 may be wireless, using a limited capacity technology such as Local Multipoint Distribution Service, relying on statistical multiplexing to support high numbers of users, and various multimedia services, eg OLME, Video on Demand (VoD) and Telephony [Lockwood & Everitt 96]. Thus as well as users competing for bits, the various multimedia services will also be competing. Most significant may be VOD, which will be conveyed in the form of Variable Bit Rate or Constant Bit Rate ATM cells, and with a Quality of Service constraint that delivery be not subject to excessive jitter. Thus at the instants when the instantaneous traffic demands on the distribution point are high, VoD traffic may have priority over OLME traffic, effectively introducing significant delay and delay variation into the OLME DDBs.

4. Conclusions

We have described a scenario in which on-line multimedia education is delivered to students at home, via a broadband wireless link. We have proposed a data transmission model for such OLME, which is very bursty. We have illustrated how the transmission network and other non-OLME multimedia services can impact on user satisfaction (and in the CDROM version have suggested various strategies to cope with these impacts). We have begun to characterise the nature of the OLME and VoD traffic at the distribution points, and the OLME throughput to individual Clients, assuming wireless ATM C links. The aim is to clarify the issues and quantify the tradeoffs, to inform the design and implementation of on-line multimedia education.

A Virtual Schoolhouse for Educational Resources

John Leddo
Research Development Corporation
jleddo@rdc.dgsys.com

Education reform is "raising the bar" for educators with challenging standards, new teaching and assessment methods and increased accountability. Technology is expected to play a key role in aiding reform. It is expected that the Internet will play an integral role in classrooms of the future. However, connecting schools to the Internet is only part of the challenge. Another part is to provide teachers and students with resources they can use in the classroom. As the amount of content available over the Internet multiplies, there will be an increasing need for teachers to find places where they can go "one stop shopping" for educational materials. The present paper describes a "virtual schoolhouse" which we are developing to serve teachers and students. The virtual schoolhouse is designed to be a repository of resources that would normally be found in a physical schoolhouse, but without the constraint that they be located within the school.

It is expected that the Internet will play an important role in the future of education. According to the American Association of School Administrators, 65% of U.S. schools have Internet access already. New schools continually connect to the Internet and educational content is created and added to the Internet daily.

As this proliferation of Internet resources continues, with anyone being allowed both to create and use content, we must not lose sight of two objectives: there must be organization to the material available and there must be quality control. One cannot simply send students and teachers into cyberspace and hope that they will find educational material that is both relevant and of high quality. Even the advent of web browsers are insufficient. For example, we entered the topic "high school science" in a popular web search engine. It returned approximately 1,000,000 matches. We then focused the search on "high school physics". A full 400,000 matches were found. The search was focused even more on "Newton's Laws". This produced a match of 10,000 responses.

We argue that such numbers will only increase as more and more people add content to the world wide web. We do not believe teachers will spend the time surfing the information superhighway looking for educational content. What is needed are organized resources in cyberspace much the way there are organized resources such as libraries, research centers and schoolhouses in physical space. These organized resources would be places on the Internet where teachers and students could go for "one-stop-shopping" and gain access to materials and activities relevant to their teaching objectives.

Research Development Corporation is currently developing a virtual schoolhouse. The goal of the virtual schoolhouse is to be a repository of educational resources for students and teachers. These could be in the form of educational research articles, curriculum materials, educational games, simulated laboratories and forums for exchange of ideas. The goal is to provide the same types of resources found in an actual schoolhouse, but without the constraint that educational resources, students, and teachers be collocated at the same place at the same time.

When completed, the virtual schoolhouse will have the following components. First, there will be a virtual library where teachers and students can read educational research findings, commentary and other relevant educational publications. The virtual library will be a place where teachers can post and download curriculum materials so that these can be shared by all teachers.

Second, there will be a chat room, where teachers can discuss educational issues in real time. The goal of this is to give teachers access to a wider range of professionals than they might find within their own schoolhouse. In our previous research (Leddo, 1995), we found that one of the biggest needs cited by teachers for their own professional development is more interaction with other teachers and related professionals.

Third, there will be a lecture hall where teachers and students can attend, at a distance, professional development lectures. We envision both real time and asynchronous modes of presentations in three forms of presentation: text, audio and video. In cases where presentations are real time, we envision teachers and students having the opportunity for "live" question and answer sessions with the presenter. Where presentations are done asynchronously (i.e., prepared ahead of time and broadcast at specified times), teachers would either have to e-mail their questions in advance or send them after the presentation for subsequent response.

The virtual schoolhouse can be augmented even further. One of the challenges developers of cyberspace learning environments face is making these environments user-friendly. A physical library is not only organized, but has a reference librarian who can answer questions, direct a teacher to relevant materials, etc. What makes a reference librarian effective is not just knowledge of the resources in the library, but the ability to understand the needs of the teacher and asks relevant questions in order to reach that understanding. We believe the virtual schoolhouse should have the same sorts of "intelligence", namely a virtual reference librarian in the form of an intelligent agent that serves a similar role.

In order to address these issues, we will present a discussion of ongoing research in several related projects. First, we are constructing a virtual schoolhouse architecture that is designed to support simulation-based learning activities with integrated intelligent agents. This architecture will support collaborative problem solving over the Internet so that students at different sites can work together. The first simulation to appear in the virtual schoolhouse will have intelligent tutoring so that students can receive remediation as part of the learning experience.

Second, we are developing intelligent agent technology to be included in the virtual schoolhouse. These agents are primarily designed to serve as co-problem solvers as they work. Agents can serve in both an instructional and assessment capacity through their dialog with students. This is discussed in greater detail in our second paper submission: "Internet-based intelligent tutoring games".

We are also serving as a repository for research papers, position papers and other reference material that might be useful to teachers.

Internet-based Intelligent Tutoring Games

John Leddo
Research Development Corporation

Educators wish students had the same interest in learning academic subjects as they do in playing computer games. Developing computer games that are entertaining, yet educational, pose technical challenges. These include developing a game environment that supports the subject matter being taught, assessing student learning from game-playing behaviors, and having game events respond to individual student learning needs. The present paper describes work to develop an Internet-based game to teach scientific reasoning. The game context is solving detective problems. Detective work is chosen for its similarity to the scientific method. Assessment of student learning is accomplished by having game characters converse with players to probe their reasoning. The scenes in the game teach different aspects of scientific reasoning. The activities and information present in these scenes are driven by student learning needs.

A Framework for Intelligent Tutoring Games.

The goal of our work is to embed high quality instruction in the context of computer games so that students can learn in a fun environment. This presents the challenge of creating games that are as fun as those that would compete for students' learning time, yet present meaningful instruction. Because our emphasis is on education, we focused on that aspect first and built the game around it.

The first step in our project was to develop a model of scientific knowledge. Since our goal is not simply to present a science curriculum within the context of a computer game but rather to build the same type of thinking skills in students that scientists have, it is important to identify those skills. Based on discussions with research scientists, we extracted the following process of scientific inquiry.

The process of scientific inquiry begins with a question. The question directs subsequent inquiries, the results of which will be evaluated according to how well they address the question. The second step is to develop a model of the phenomenon in question. Very often, scientists cannot directly observe the phenomenon they are investigating. As a result, scientists develop models that represent their best approximation of the phenomenon. Often, investigations look for ways to test these models. The third step is to develop hypotheses that represent possible answers to the question. These hypotheses must have observable consequences, and the observable consequences of different hypotheses must be different. The fourth step is to collect data or evidence to distinguish among the explanations or hypotheses being considered. This step is a key discriminator between successful and unsuccessful investigators. Effective information gathering requires understanding what types of information discriminate among the hypotheses, and knowing how to collect this information. The fifth step is to analyze the data in order to come up with results that would be relevant to the hypotheses under consideration. This requires not only knowledge of the mechanics of analysis methods, but also the ability to select an appropriate analysis method for the problem at hand. The final step is drawing conclusions about the hypotheses in the light of the evidence collected. This involves determining which hypotheses are best supported by the evidence and whether that support is strong enough to draw a definite conclusion.

Once we established the concepts we wanted to teach students, we selected a game context. Our goal was to pick a context that lent itself well to both a game and the subject matter. We chose solving detective stories given the parallel between how scientists and detectives think. The table below illustrates this parallel.

Scientific Reasoning	Detective Reasoning
Formulate a question	Who "dunnit"?
Develop hypotheses or models to answer question	Find suspects, develop scenarios about how crime was committed
Gather information related to hypotheses	Collect clues
Compare measurements to predictions of hypotheses	Forensics; comparison of clues to scenario predictions
Draw conclusions	"Beyond reasonable doubt"

Table 1: Scientific Reasoning vs. Detective Reasoning

Based on the above analysis, we can create detective stories that make teaching points regarding scientific reasoning. For example, we can create stories with multiple suspects to teach students how to gather evidence that will distinguish which is the guilty one. This is analogous to having multiple hypotheses that a scientist must collect data for in order to distinguish which one is likely to be correct. We can manipulate the number of clues or their reliability in order to make teaching points about how it is important to collect sufficient data and how biased data can distort one's conclusions.

An Internet-based Intelligent Tutoring Game

A prototype of an intelligent tutoring game has been developed and placed on the world wide web (WWW). It can be accessed at http://www.RDCPublishing.com. In the game, the student joins a team to solve a mystery. The teammates serve as co-problem solvers as well as mentors when the student needs instruction.

The game is written in hypertext markup language (html). The student views each screen and then clicks a forward or backwards arrow to move through the story. At several points in the story line, the student is asked to make decisions. These could either be decisions with respect to what path to follow in solving the mystery or to perform quantitative problem solving. The choices the student makes will influence what path the story takes. In the cases where students are asked to solve problems, their answers are used to assess whether they need any remedial instruction. In cases, where remedial instruction is provided, students follow a separate branch of instructional activities off the main story line. Upon completion of the remedial activities, they join the main story line in the place they left off. The student then follows the story line to its completion or until additional remediation is needed. By the time the student reaches the end of the storyline, s/he will have completed the enter lesson embedded in the story as well as any remediation that was required along the way.

EDUNET Global Learning Resources Development Project: What We Learned from Creating Our Homepage with Others' Web Resources

In-Sook Lee, Ph.D
Office of Int'l Research Cooperation
Korean Educational Development Institute
Republic of Korea
inlee@ns.kedi.re.kr

Abstract: To date, most global resources on the Internet have rarely been of practical value to Korean schools and learning communities. This is due to the fact that they are in English or other commonly used foreign languages and reflect cultures and curriculum that are quite different from those of Korea. The EDUNET Global Learning Resources Development Project was launched in June 1996 in order to create an open environment which promotes accessing and using valuable global resources. The homepage developed in the project provides a variety of learning and instructional resources selected and slightly modified from resources on other web sites around the world. Based on the experiences of the current project, the following is suggested for ensuring better quality service development: (1) Long-term and comprehensive initial development plan, (2) Responses to dynamic and evolving features of the Web, (3) Management for obtaining copyright release, and (4) Management system for quality translation.

Introduction

The Internet has transfigured the images of both learning time and learning spaces by expanding the walls of traditional classrooms out to the global world. It has significant potential for creating a new educational system through the establishment of learner-centered, open learning environment [Lee 1995; Lee 1996]. To date, however, the majority of global resources on the Internet have rarely been of practical value to Korean schools and learning communities. This is due to the fact that they are in English or other commonly used foreign languages and reflect cultures and curriculum that are quite different from those of Korea. Due to those differences, the teachers and students have experienced difficulties accessing and using valuable global resources.

Overview of the EDUNET Global Learning Resources Development Project

The EDUNET Global Learning Resources Development Project was launched in June 1996 with a budget of roughly $ 130,000, and ended its first development in December of the same year. The homepage developed in the current project provides a variety of learning and instructional resources selected and slightly modified from resources on other web sites around the world. The resources embody lesson plans and learning resources in the primary subject areas at each school level. They cover various media formats, including text, image, graphic, audio, animation, and video. There are 207 resources listed in the homepage as of December of 1996.

Strategies for Quality Web Resources Creation using Culturally and Linguistically Different Web Resources

Based on the accumulated experiences stemming from this Global Learning Resources development process, the following strategies for ensuring higher quality service development from culturally and linguistically different Web resources are suggested:

1. Long-term and comprehensive initial development plan

Comprehensive planning at the outset is very important for having a total picture of the development budget and timline. General steps to be considered in the planning include: needs analysis, curriculum analysis & sample Web sites analysis, Web resources selection & copyright release acquisition, related data download & translation, digitalization & remaking all data into HTML. First and foremost, a development team should arrive at a clear and shared consensus on whom perspective users are and the specifications and extent of which subjects should be served.

2. Responses to dynamic and evolving features of the Web

Metamorphic features of the Web. Most Web sites are periodically revised either in their contents or structures. Modification or elimination of original Web sites imply potentially serious problems in generating time and financial loss. Considering this nature of the web as well as a never-short remakes cycle, one realistic solution is to download all original sources at the outset and keep them until translation is finished.

Interactive features of the Web. Web sites increasingly provide interactive services such as form, discussion, feedback, user-directed activities and so on. For now, it appears a challenge to provide original site's feedback in a local server corresponding to user's input for two reasons: One relates to a technical issue, the other to experts. Responding to user's input will require additional efforts in programming such as software solutions like CGI at a local site. In addition, it requires a local site to retain content experts capable of responding to user's input. Without ensuring those solutions, interactive features at original sites inevitably will be lost at local sites.

Hypertextual features of the Web. Due to differences in cultures, not all information at other web sites would be beneficial for local users. Instead, partial use of a web site is recommended. For this case, special attention should be paid on fluent reconnection among relevant hyper-linked parts. In addition, many instructional phrases, icons, and directions may need to be deleted or revised to make sense.

3. Management system for obtaining copyright release

It is a time-consuming and labor intensive process to obtain a copyright release. Well-organized and continuous management is a must to contact copyright owners and comprehend the correspondence contents. Among other management responsibilities: it is necessary to keep recording for on-time and efficient communication, and to maintain serious reviews of correspondence.

4. Management system for quality translation

Acceptable quality translation of resources is the eventual factor which decide the quality of local web sites. However, many subject matter experts such as school teachers, lack advanced skills in English translation; expert translators do not have knowledge in specific subject areas. The quality of any resources, however, will primarily depend on the quality of translation. Therefore, we need to establish a management system that will ensure the cooperation of experts in subject and translation.

ABSTRACT

A multimedia CD ROM and Web-based version of the "Information Warfare Multimedia Aid" have been developed at the US Army War College. This tutorial is geared for introducing the concepts, points of view, and players involved in defense-related information warfare. In designing this system, some interesting features were incorporated into this aid. This paper discusses these special features that other multimedia designers may want to include in their systems.

1.0 Description of the "Information Warfare Multimedia Aid"

"Information warfare" is considered one of the biggest threats in today's and tomorrow's society. In order to better acclimate senior leaders to the issues, weapons, countermeasures, and points of view relating to information warfare, the Information Warfare Multimedia Aid (both CD ROM and Web version) was developed and circulated to key individuals and organizations in the U.S. (Liebowitz, 1996). This program was developed in six months using Authorware Professional 3.0 as the multimedia authoring language. The program used a leading expert in information warfare as the content specialist. The program consists of ten modules discussing introductory concepts, threats, weapons, political issues, defense-related perspectives, recommendations, and conclusions. Video segments, hypertext, sounds, voiceovers, graphics, and animation are used in the system.

2.0 Useful Features in the Information Warfare Multimedia Aid

2.1 Tailored Modules

The Information Warfare Multimedia Aid uses tailored navigation to recommend which modules, and in what detail, would be best for the user to review. The system asks a series of questions, based upon the user's background and interests, at the beginning of the user session. Accordingly, the recommended module names are underlined in red in the table of contents and once the modules are reviewed, the module names are highlighted in green.

2.2 Cases and Vignettes

In order to better understand future implications of information warfare activities, cases and vignettes have been included in the Information Warfare Multimedia Aid. The cases and vignettes enhance the conceptual material and reinforce the issues in a realistic way.

2.3 Interactive Exercises

A variety of interactive exercises have been included at the end of each module, if the user wants to "test his/her knowledge." Every exercise gives the user two tries to get the correct answer, and then the correct answer is highlighted with a brief explanation of why each response is right or not. At the end of the module post-test, a score is computed with a graphic representation of the number of correct and incorrect responses.

2.4 Annotated References

A list of close to fifty references with associated brief descriptions have been provided in the "Reference" section of the Information Warfare Multimedia Aid.

2.5 Glossary

The Information Warfare Multimedia Aid contains a glossary that can be accessed any time to get definitions of words, acronym meanings, and points of contact at different agencies. The glossary also contains a "find" feature to locate words in the glossary.

2.6 Excel Appendix

An Excel executable which can be invoked in the Information Warfare Multimedia Aid contains organizational charts of companies and agencies performing information warfare work.

2.7 Quick Question/Answer Expert Advisor

Another value-added feature incorporated into the Information Warfare Multimedia Aid is an expert system quick question/answer advisor on information warfare. This component was built using Exsys Professional as the expert system shell. It can be invoked any time, and allows the user to get quick, informative answers to questions about information warfare.

2.8 Executive Summaries

Executive summaries of each module are included in the system. The summaries are concise and give excellent overviews of the salient points in each module. There is a "print" feature to print out the summaries in case the users want to review them at their leisure.

2.9 Voiceovers with Highlighted Text

The Information Warfare Multimedia Aid is rich with voiceovers with highlighted text used throughout the tutorial.

3.0 Summary

The initial feedback of the Information Warfare Multimedia Aid has been very positive, especially with the value-added special features discussed in this paper. These features have certainly enhanced the multimedia system, and other multimedia designers should strongly consider incorporating such features in their systems.

Abstract: This presentation reports the authors' experience in engaging high school students as multimedia designers in a simulated multimedia production house for the second year. It describes the multimedia design model used, its implementation and the evaluation of students-created multimedia products.

Theoretical Perspective

For centuries, learning by doing has been perceived and used as an effective instruction model. It has been used in a variety of disciplines with success [Collins, Brown, & Newman, 1989]. The recent advancement in interactive multimedia/hypermedia technology has demystified the technology in such a way that it makes it possible for learners, elementary or high school students, English or computer science majors to have the power of designing multimedia programs and be a multimedia developer. Literature and research have shown that engaging learners as designers of multimedia programs has the benefit of not only enhancing their motivation but also promoting their higher order thinking skills [Lehrer, Erickson, & Connell, 1994; Perkins, 1986]. Being a multimedia designer, a learner is given the opportunity to research, design, and create. A number of studies on the topic have shown some preliminary success [Carver, Lehrer, Connell, & Erickson, 1992; Lehrer, 1993; Liu & Rutledge, 1996].

Multimedia Learning Environment

High School Students

This experience of engaging high school students as multimedia designers occurred during the Fall 95 and Spring 96 semesters. The participants were from an inner-city minority dominant high school in a Southwest city. They were twenty-six 10th-12th graders enrolled in a multimedia design class (Caucasian = 29%, Hispanics = 52%, African American = 10%, other = 9%). About 60% of the school population are considered to be at-risk for not finishing high school.

Multimedia Design Model and Its Implementation

This multimedia course is a year-long one. It uses a four-phase design model [Liu & Rutledge, 1996]. It includes (1) planning, (2) design, (3) production, and (4) evaluation and revision, based upon the practice used in the multimedia industry [McDaniel & Liu, 1996]. The first semester focused on learning the basics of multimedia design and various tools. They started with simpler multimedia programs and then moved to more complicated multimedia software. Students completed most assignments on an individual basis. During the second semester, while students continued to learn multimedia tools, the focus of learning shifted to collaborative work. Students were given the opportunity to work with a client and design for a real audience. After several brainstorming sessions, students formed groups of their own interest and proceeded to work collaboratively. One group worked with Texas Parks and Wildlife department to create a multimedia kiosk. One group worked with a university graduate in creating children programs using original songs. Two other groups chose to work on a poet story and a football program. Each member of the team was assigned a role of a researcher, graphic artist, programmer, project manager, or animator for their project. They were engaged in creating storyboards, researching, and producing the programs. They learned the state-of-art multimedia tools. Three people from Texas Parks and Wildlife department and one graduate student worked closely with two teams. The teacher acted as the project manager for the entire class and provided guidance especially to the other two groups. During the semester, students made trips to local multimedia companies, made presentations at a multimedia users group meeting and had local multimedia experts visited the classroom. Several factors characterized this environment. The design process was made explicit through (1) direct instruction by the teacher, (2) interaction with local multimedia experts, and (3) assessment used. Student learning was scaffolded by (1) explicit design instruction, (2) learning multimedia tools, (3) coaching by the teacher, the peer (the more experienced students), as well as the clients.

Students met as a class for one hour and half everyday for a total of eighteen weeks per semester. They had accessed to five Power Macintosh computers, two Mac LCIIIs, two Mac 575s, and one Mac 520. A PowerMac with video digitizing and editing capability was acquired in the second semester, but was no longer used after its tape deck was damaged. Seven of these computers had adequate RAM and disk space for using software like Photoshop, Premiere and Director. One PowerMac with sufficient computing power was assigned to each group. Students in the group, therefore, had to take turns to use this computer.

Technical Skills Acquired and Multimedia Programs Created

At the end of the year, all students had a good command of Claris Works, SuperPaint, HyperCard used in the course. Some students were very proficient in Adobe Photoshop, and Adobe Premiere while others were good at Macromedia Director. In addition, students used Ofoto for scanning, and SoundEdit 16 for audio digitizing and editing. One group used Strata Studio Pro, a sophisticated 3D rendering program extensively. Students' command of the multimedia tools was reflected in their ability to explain various features of their programs, such as the choices of media, fonts, metaphors, and their ability to demonstrate how to execute certain techniques during the presentation at the end of the year. Their competence with the multimedia tools was also reflected in the four programs they created. Students created: (1) a multimedia kiosk for a park, which provides text, video, and graphic information about birds, snakes, mammals, endangered species and plants in the park; (2) a children's program which used five stanzas of the song "I wanna be a dog" to teach vocabulary through animation; (3) an Edgar Allen Poe program, which presented Poe's poems and a story in a 3D environment; and (4) an NFL football program. It is worth noting that although some video clips were supplied by the clients, students created most of the graphics, audio, and video from scratch. The clients and the teacher were very satisfied with what the students accomplished within the time frame. The clients especially were "really impressed" with students' work and expressed their desire to continue working with the class.

Students' created multimedia projects were demonstrated and discussed. The experience of engaging high school students as multimedia designers and lessons learned from this experience were shared in detail.

The Provision of an Open Access CAL Resource Base.

Dr R M Lloyd, School of Engineering, Cardiff, University of Wales, UK. LloydR@cf.ac.uk
Dr C J Moore, School of Engineering, Cardiff, University of Wales, UK. MooreCJ@cf.ac.uk

Abstract

Cardiff School of Engineering has recently appointed a dedicated Teaching and Learning Technology Support Officer. This has resulted in a unified resource base which has been implemented for open access and has required the development of a generic front end system to enable the inter-operability of CAL tools with differing / conflicting software requirements.

This paper outlines the development of the resource base and reports on the problems encountered in this process. The paper introduces recommendations for the future development of academic CAL material designed for open provision.

Background

The UK has benefited enormously from the Teaching and Learning Technology Programme (TLTP), whose projects have involved consortia of Universities producing CAL material to cover a wide spectrum of subjects. TLTP material must be made available to all UK HE institutions at distribution cost. TLTP therefore represents a major source of academically validated CAL material. To the funding councils however, TLTP represents a substantial investment. Clearly both the funding councils and the institutions expect to see a measurable return on this investment.

The Cardiff School of Engineering is a member of a TLTP Engineering project and as such has contributed [1,2,3] to the development of 60 CAL modules covering a range of engineering subjects. The current project, 'The Cardiff CAL for Engineering Project', continues the School's involvement in CAL. The project is based upon the School's need to utilise CAL to enhance teaching quality and learning, meeting demands for the effective utilisation of technology and providing support for staff wishing to embed CAL within courses.

The primary objective of this project is therefore to implement a resource base of suitable CAL material for use in the School's teaching and to encourage the uptake of material by staff and students. To achieve this, the key activity is to establish an open access CAL resource base, supported by a range of facilitation initiatives, which include a CAL newsletter, a WWW site and support workshops and lectures.

The CAL Resource Base

The resource base will comprise all appropriate TLTP material, material from other academic sources as well as suitable commercial material. Initially only PC based material has been considered. This is to ensure that the depth and the scope of material is developed quickly, to enable fast and effective utilisation and that the material provided originates from validated sources. Also, all material must be run on a standard platform and accessed from PC based file servers. The current resource base consists of a range of software, covering such diverse areas as Mathematics, Materials and Electronics.

Figure 1: The Generic Front-End System.

Integrating the CAL Packages

The lack of development standards and the range of approaches taken in the development of CAL packages has resulted in packages with conflicting configuration requirements and disparate operational modes [4]; problems which are emphasised in network implementation. Clearly an initial requirement at Cardiff was to develop a framework for the integration of a diverse range of packages into a unified resource base. To this end a generic

BEST COPY AVAILABLE

front-end has been developed from which all CAL packages can be accessed (Fig. 1). This fulfils four primary requirements:

1. It provides a unified interface to modular CAL packages.
2. It enables the dynamic configuration of packages within the Windows environment.
3. It provides centralised monitoring of package usage.
4. It assists in the management of the resource base by centralising individual CAL package specifications.

Initial Results

The implementation work described and the supporting awareness raising initiatives have been developed over approximately 18 months. Results demonstrate the potential benefits of this project, as 14% of the School's lecturers began to use CAL as a result of the material being promoted. An additional 29% indicated that they would like to use CAL if appropriate material were to become available. CAL was used on 12 of the taught courses and approximately 3350 student hours were spent on CAL in one year.

Reactions were elicited from students by a simple questionnaire and were generally very favourable. Figure 2 shows the average reactions of 79 students to a CALGroup module on beam bending theory:

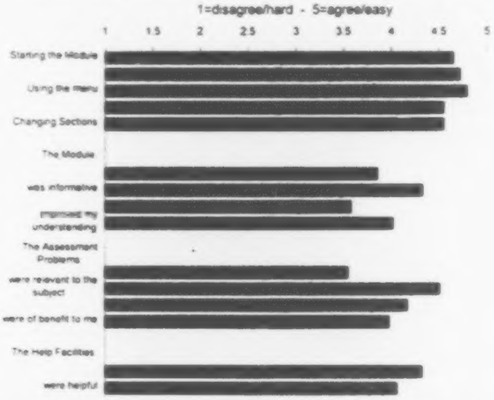

Figure 2: Student Reaction to the CALGroup Beam Bending Module

Whilst these initial results are encouraging it is anticipated that the significant increase in the range of material available for the current academic year and the increased effort being directed towards the promotion of CAL will result in a proportionate increase in uptake both amongst staff and students.

Summary and Recommendations

The Cardiff CAL for Engineering Project is a model based upon the belief that CAL is best implemented by dedicated support staff working closely with teaching practitioners, within specific subject areas. Institutionally, this model could be extended to incorporate several such officers working within carefully selected disciplines; and administered by a central manager. Whilst not the cheapest option, it is likely to succeed in its aims.

The success of CAL as an educational medium clearly relies upon successful implementation. Developers of CAL material should be aware of these implementation issues, to ensure that their software can be implemented with minimum complexity and in a wide variety of infrastructures, with particular reference to:

- Ensuring that CAL software is as stand alone as possible and minimises the need for special configurations.
- Ensuring that modular CAL packages can be used independently and in isolation from any front-end.
- Enabling the local configuration of all file locations and data output paths.
- Providing any user progress and performance monitoring data is a clear and intuitive format.

In the longer term, this paper agrees in principal with the findings of the TLTP EPOC report [4], in the need for software standards for CAL material intended for open provision.

Abstract. This paper will describe the experience of the joint project, having the same name, developed by two groups one from the Institute for Experimental Physics, University of Kiel-Germany and the second from the Computers in Teaching Initiative Pilot Centre, University of Bucharest-Romania, in the fields of microcomputer based experiments and computer aided teaching / learning in Physics.
A number of *PADI Systems, hardware and software:* were produced: they are able to measure directly and to store in computer a great number of experimental data but also to perform on-line measurements (voltage, time, frequency, resistance, capacitance) and to perform analysis like FFT-Fast Fourier Transform. Non-electrical quantities like pressure, temperature, light, intensity of magnetic filed or induction etc., can also be measured with PADI Systems connected to different sensors, which are able to provide as output an electrical voltage.

Microcomputer Assisted Experiments.

Today it is absolutely necessary for scientists and engineers to use data acquisition and computer analysis in the case of huge amount of experimental data as well as for every day use in their laboratories. For the same reason students should have the chance to learn how to handle the existing products as well as to design and to produce their own according to their needs and financial possibilities.
The main goal of our project was to design and test new solutions for microcomputer assisted measurements as low cost, efficient and elegant alternative to the classical measurements, acquisition, analyze and storage of physical data within the laboratories which can not afford big investments in expensive equipment (schools, universities, some research laboratories).

As a result of the project a number of *PADI Systems* were produced. They are able:

- to measure directly and to store in computer a great number of experimental data but also to perform on-line measurements (voltage, time, frequency, resistance, capacitance) and to perform analysis like FFT-Fast Fourier Transform;
- to measure non-electrical quantities (like pressure, temperature, light, intensity of magnetic filed or induction etc.) using additionally sensors, which are able to provide as output an electrical voltage;
- to perform the remote control of the industrial processes due to the D/A-Out (digital to analog) and D-Out (digital) output channels provided by the PADI interfaces.

The *PC plus the PADI System* is working like an *Oscilloscope with memory* handled by software: the analog experimental data are subject of A/D conversion, then they are fed into the microcomputer, they are displayed/measured or stored on the hard disk for analysis with specialized software (MS-Excel, Microcal Origin etc.). The actual hardware interfaces are connected on the parallel port of a PC IBM-compatible. User friendly software interfaces, GUI type, were prepared in order to run on powerful PCs with Pentium processor and Windows environment as well as on old PCs with 80286 CPU and DOS operating system.

We have designed and tested the following *PADI Systems*:

- 2-channels Oscilloscope working in the range 0÷5 kHz,
- 1-channel Oscilloscope for 1 MHz,
- Multimeter interface,
- 4-channels Timer,
- Steeper motor and Relays interface,
- 1-channel Oscilloscope for 100 MHz (is under way).

Computer Aided Teaching / Learning

One of the most attractive applications of simulation software is in university education because an extremely large range of problems involving very complex system of equations can be easily studied in detail.
The problem is to choose a correct strategy and a good balance between physics and mathematics. A large number of textbooks present numerical algorithms in details and assume the reader to make programming, to write their own lines of codes. The specialists in programming spend years learning the tricks, preparing a good interactive software, maximizing the graphics capabilities and all these things in real-time computation.
That is why we prefer to use advanced software packages which save the students and teaching staff to worry about detailed numerical algorithms and programming and allow them to concentrate on fundamental aspect of Physics. We use in our laboratories powerful tools for simulation and for doing the mathematics necessary for teaching Physics: Derive for Windows, Macsyma and PDEasy which allow the students to perform fast computation, to produce accurate solutions and graphical outputs.

For teaching/learning purpose we are just preparing software packages according to the Romanian curricula but we are also using some of the currently available academic software dedicated to Physics: SToMP package produced by the CTI Physics Centre-University of Surrey UK, PAS-Physics Academic Software, Interactive Physics(IP) and CUPS series. All the time the results of simulation are compared between them and with experimental data, when available.

As it concerns the teaching/learning activities within the Romanian universities and schools, we believe that one computer image has an impact which is stronger that 1000 words and therefore, we have to stimulate the involvement of the teachers and staff in using a good academic software.

Conclusions

- *this paper clearly reveals our willingness to adapt to changing conditions in education field especially to the emergency of the Information Technology;*
- *there is a need to optimize the use of microcomputers in education by improving the access to good and cheap hardware and software;*
- *the computing resources can be maximally exploited not only for informatics field but also for mathematics, physics and other natural sciences*
- *there is a requirement for the decision-makers at institutional level to encourage the use of computers in order to enhance the quality of the teaching/learning process.*

Acknowledgments.

We are grateful to the Volkswagen Foundation in Germany for funding support under which the fruitful cooperation between the two teams in Germany and Romania was possible.

Computer-Assisted Failure (CAF)

DANIEL LUTZ
Managing Director, Human Shareware
The Netherlands, <humans@euronet.nl>

Abstract: Computers offer great potential to revise the way we approach education. With the digitalisation of information, and the ability to manipulate this information on computers, the way is open for revised models of learning. One such model is "Computer-Assisted Failure" (CAF), since it is precisely through a process of structured "failing" that computers offer students greater learning opportunities. Educators need to re-asses the educational value of "failing" and, using the appropriate hardware and software, incorporate this model of learning into their curricula. This paper looks at the ability of well-designed computer programs to foster creativity, initiative, and critical thinking, arguing that these skills are essential to our modern society.

Breaking the "Success Cycle"

A typical western student's education looks something like this:
Beginning sometimes as early as middle school, students get streamed into those subjects for that which they show most aptitude. Teachers, parents and guidance counsellors offer encouragement to continue in those courses. Positive feedback reinforces an increasingly focused group of skills, while negative feedback, in the form of comments, as well as poor marks, weeds out less proficient skills. As the student moves up the educational ladder, grades become more important. At the same time, the basis on which these grades are judged becomes smaller, sometimes being represented in a 100% final exam. For those who want to move on to higher education, grades become critical in the last few years of high school. The result is a proficient graduate, conscious of his/her abilities, and able to work under pressure. Or, viewed in a different light, the result is a too-specialised graduate, versed in a narrow range of skills, who is poorly trained to take risks.

Traditional structures of education and assessment favour a "cycle of success", a pattern in which students are streamed into areas that they do well in. On the one hand this would appear logical, as well as sensible. Schools, after all, are expected to turn out well-educated and capable young members of society. By focusing on what they do best, schools are merely maximising the potential of each of its students. On the other hand however, such a narrow focus on the part of schools creates graduates untrained and unprepared for failure. Students graduate with an underdeveloped ability to take risk and initiative, and having developed and explored only a limited part of their creative range. Traditional educational values would suggest that there are few instances where a "fail" is regarded positively. The basics of teacher training is to do everything to prevent "failing" in their students. On a practical level, teachers do not have the time to engage in a process of trial and error with every one of their students. Yet in the kind of society we now face, where developments are measured in weeks and months rather than decades and generations, the ability to take risks is crucial. And one does not learn properly to take risks without having learned the essential skill of failing.

Supporting Structured Failure

The use of computers in education is not a new phenomenon. For quite some time now, computers have been used for simple, straight-forward assessment. A right or wrong answer to a mathematical question, for example, is better, more quickly and reliably performed by a computer than by a teacher. The benefit to the teacher, in terms of a reduced assessment load, is obvious. Increasingly, computer programs are becoming capable of assessing more than a simple mathematical, or letter-based answer. However, if the "cycle of success" is to be broken, than computers have to become involved not only in assessment, but in the teaching process itself.

The digitalisation of information, and the ability to manipulate this information on computers has given students unprecedented control over their own learning. In principle, a virtual learning environment can be accessed anywhere, taken anywhere, expanded, created and destroyed at will. Experiments that previously might have had to take place in a laboratory, with limited access and expensive equipment, can be completely simulated on a computer. Furthermore, with a well-designed program, a student can go backwards and forwards in a given experiment, controlling the experiment in a way not possible in the "real" world. Students, freed up from having to worry about using up costly materials, or blowing up the school lab, can work through an assignment multiple times, even improvising or adapting the original task in order to expand or test newly acquired knowledge.

With well-designed software, computers can offer intense one-to-one support, either in the form of a "intelligent computer agent", or in a database which records a student's progress through the program. The latter allows instructors to be "virtually present" during each and every students working process. As many distance-learning projects have discovered, there is great potential in the fact that students and teachers no longer have to occupy the same physical space in order to communicate with each other. For the student, expert assistance need only be an email away. No teacher is an expert on all subjects, and the ability for a student to easily seek out other advice or knowledge can only be seen as a positive advantage to the learning process. Well thought-out and expertly researched software programs, can offer every student the best learning materials and formats available. As computers become increasingly networked, these programs can plug into a limitless number of databases, many offering up to the minute data.

How does all of this create a situation in which the student is not only allowed, but encouraged to fail? The answer is better contextual learning, which is exciting and to which the student can relate. Computer programs can offer students one-to-one structured guidance while still allowing for a great deal of individual freedom and exploration possibilities. Such a structured interactive world can actually train students to take risks. In fact, well-designed programs intend that the user "fail" at some point. By building in incremental levels of difficulty, students rise to the level of their own ability. If the program is well-designed, than students will have to "fail" a few times before pushing on further. I am not talking about the high learning curve which discourages people so much that they end up quitting in despair. I am talking about highly structured, carefully supported, failure. Failure then, changes from being something negative to something positive; a challenge to push on to a higher level of understanding.

While most games offer only a limited, if any, amount of true educational content, for educators there is much to be learned from a gaming paradigm. Game designers know only too well the importance of building in incremental levels of difficulty into a game. There is no reason that this same approach cannot be applied to truly educational content. In essence, good game design requires only that that there is a clear challenge for the user, and that the user is furnished with the necessary tools and information to finish the game. Within that basic structure, there should be exciting things to discover, sudden surprises, and difficulties to overcome. In actuality, the discipline of designing a good game is very similar to the discipline of designing interesting and effective lesson plans. Sound, graphics, and animations do not have to be gratuitous "bells and whistles", but can offer important feedback and information.

Computer-assisted evaluation can also be used to encourage "failure". Software can be designed to record a student's progress through the program, allowing the instructor to evaluate the process rather than the final result. For the teacher, this allows insight into a student's working/thinking, and hence learning, process. Areas of weakness, or misunderstanding can be picked out, sometimes just by seeing where a student became stuck, and what choices were made at given points. The student is given even greater room to fail if the program is structured on a "complete/not complete" model of evaluation. In this model, it is not possible to complete the program, unless a certain level of understanding has been reached. How that level of understanding is reached, or how long, or how many tries it takes is of little or no importance. What is important is that the student comes to understand something new. Failure needs to be considered an integral part of the learning process, and not something to be avoided.

By providing virtual environments in which to explore, one-to-one attention, tracking programs, and the ability for people to manipulate and send data easily, even over long distances, computers can greatly support a model of education which encourages structured failure.

Developing an interactive computer-aided learning suite using a LAN-based Video-on-Demand and a World Wide Web system

Stephen Mak
Department of Building and Real Estate, The Hong Kong Polytechnic University
Hong Hom, Kowloon, Hong Kong
E-Mail: bssmak@polyu.edu.hk

Abstract:

Integrating the emerging video-on-demand (VoD) technology with the Web system and local area network (LAN) which are well established in the Department of Building and Real Estate (DoBRE), the proposed research project aims to develop multimedia, interactive, and self-directed learning units for the subject in Construction Technology. The completed system can deliver more than 40 multiple video streams simultaneously within the host Department's network. Also, a stand-alone version of the completed system can be produced on CD-ROM format to benefit a wide group of users. Once developed and demonstrated the technology can be adapted and applied immediately to other subjects, such as Project Management, and Real Estate Marketing; and later extended to other areas where this type of learning is effective. The successful completion of the project should lead to an improved and innovative way of teaching and learning.

Introduction

This project aims at developing multimedia, interactive and self-directed computer-aided learning units for the subjects in Construction Technology, and Construction Management.

Learning Objects

- have continuous access to video clips showing the different construction processes, methods and techniques,
- observe more "real life" construction processes and techniques than are practically possible by field trips,
- interact with the program, ask and answer questions. Students will be given remedial help from the system if necessary.

Technical Objectives

- produce video recordings of actual construction operations to help students visualise different kinds of construction process, methods, plants and machinery;
- convert the video recordings into digital formats for storage in a computer system for self-directed viewing via a Video server and a World Wide Web server;
- develop a series of complementary course notes for the video recordings in hyper-text and graphical formats via a Web server;
- develop a series of interactive self-review exercises and tutorials via a Web server with a database link;
- exploit the capabilities of the department's well-established networking system (ATM and switched fast Ethernet) and Internet servers (3 Web servers and 2 database servers);
- integrate a LAN-based Video-on-Demand (VoD) system with the Web system in such a way that multiple video signals (streams) can be delivered concurrently to different students via a common graphical user interface, i.e. a Web browser (it is estimated that more than 40 video streams can be delivered simultaneously within the department's network);

Background Information

Typically construction related subjects are taught conventionally in a lecture and tutorial format. Over the years students have expressed their desire to have more opportunities to actually visualize and conceptualize the various construction processes a nd management techniques. The difficulty of teaching these subjects effectively supports this point of view. Whilst site visits, field work and case studies can provide some opportunities for students to visualize these processes, they are far from ideal and are not always feasible due to large class size, tight teaching schedules, inconvenient timing, and location. Video taping the actual construction activities and converting them to digital format so allowing students to view these activities using a series of interactive tutorials via a Web server can provide a better learning facility for the students.

Methodology

The project will draw extensively on both equipment and expertise. However, the Department of BRE is in an advantageous position to develop this system due to its well-established local area network (LAN) which incorporates fast Ethernet switching. This LAN, hence, enables it to enjoy considerable additional benefits by putting in just marginal investment. The process of the project is summarized as follows:

- Subject lecturers will be involved in deciding which areas of the Construction Technology, and Real Estate Management units will require video support and contribute to the development of the subject materials.
- Education technologists will be involved to help design the learning unit. They can also contribute in designing both summative and on-going evaluation of the learning unit. Information technologists will be responsible for setting up the VoD server, developing algorithms for the interactive and multimedia contents on the Web server. Media specialists will help edit and convert the video contents into digital formats.

Evaluating the success of the project

The project can be evaluated by 4 means. Firstly, direct feedback through face-to-face discussion with the students will be conducted regularly to ensure that the developed system actually meets the needs of the end users. Secondly, a user-oriented questionnaire will be designed in consultation with education technologists (our input from the Education Development Unit) to solicit opinions from the end users. Questionnaires can be distributed both electronically through the Web server or manually to the students undertaking the learning units. The aim is to ensure that adequate and representative samples can be obtained from the population. Thirdly, a log of Web hits can be recorded and random statistics inspected to reflect the frequency of utilization and the popularity of the system. Lastly, the development process, lessons learned, and the effectiveness of the developed units will be documented and published in international journals of higher education teaching to facilitate a world-wide forum on the project. It is expected that a proper peer-group assessment as adopted by most refereed journals can provide a fair and reliable evaluation to the success of the project.

Conclusion

The department of Building and Real Estate has been investing fairly heavily in constructing a robust and scaleable infrastructure for information technology and is looking forward to enjoying the benefits. Although the context of this project is in construction, we found it totally feasible to adapt the technology in any other subject areas. We are developing applications for real estate marketing and management with decision making processes and simulated role-play sessions built-into the learning units. If it could be delivered by cabled TV system, its contribution to distance and open learning will be even more enormous.

Problem Solving in a Multimedia Environment

Catherine Vadala Maltbie
Daniel D. Wheeler
University of Cincinnati
Educational Studies Division
Mail Location #0002
Cincinnati, OH 45221-0002 USA
e-mail: Cathy.Maltbie@UC.Edu
e-mail: Dan.Wheeler@UC.Edu

Abstract: Computer systems are increasingly useful tools in the teaching and learning process. Teachers can utilize software to expand upon an idea, to provide practice, and/or to give students limited access to an experience which would be otherwise unobtainable. This study looks at how the multimedia program *Myst* can provide learners with an opportunity to obtain and utilize information so that problem solving can occur in a rich, simulated, environment. This kind of environment is becoming increasingly important in education as teachers attempt to implement active learning projects under the influence of constructivist and situated cognition ideas.

Introduction/Theoretical Frameworks

Problem solving research is a highly developed and important area of research in psychology and education. Critical thinking and problem solving skills are prominent national educational goals. Currently, most problem solving research has dealt with either experimenter presented problems which are simple and easily repeatable [Newell & Simon 1972] or real life situations which are complex and unique [Lave & Wenger 1991]. This study used the popular multimedia game *Myst* [Broderbund 1994] to provide a complex, yet fully specified, problem solving environment. The total group of situations was constant, because the CD-ROM is fixed, but each user experienced a different subsegment of situations at any given time. This study was guided by the general expectation that a detailed examination of the subjects' exploration of the *Myst* world would reveal both common strategies and consistent differences in their approaches to learning and problem solving. Understanding both the similarities and differences is important for guiding the development and use of multimedia for education.

The study discussed here has many theoretical homes. Methodologically, this study was a qualitative case study with roots in the process-tracing approach pioneered by Newell and Simon [Newell & Simon 1972]. The theoretical background for this study is grounded in cognitive psychology, constructivism, and situated learning. Additionally, recent problem solving research was extremely influential during the data analysis, especially the literature on experts. The two informants were both skilled problem solvers in non-*Myst* domains. The informants progression from novice to non-novice *Myst* problem solvers was the focus of data analysis. Expert and novice problem solving has been extensively studied [Chi et al. 1988]. General conclusions indicate that increased domain-specific knowledge, organization of this domain-specific knowledge, and the identification of problem constraints are the main parameters that separate experts and novices in problem solving.

Research Methods

This research used the *talk-aloud* method for research [Ericsson & Simon 1993]. Very detailed observations were recorded of a small number of subjects as they played *Myst*. The resulting protocol was then analyzed extensively. *Myst* is a very popular commercial computer game with a reputation for breaking new ground in interactive multimedia technique. When the program begins, the player is transported to a small island with several buildings and mysterious items. The player clicks with the mouse to manipulate the objects that appear on the screen and to move from one view of the island to the next. Playing the game consists of figuring out what all the items do and how to use them. Two university-aged informants, one male and one female, volunteered to serve as informants. Both informants could be considered experienced problem solvers in non-*Myst* settings.

The informants played *Myst* in the researcher's home computer room for six sessions each. A VCR recorded all the players' movements while using *Myst*; the computer screen output was the video input and the informants' *talk-aloud* comments were the audio input. The informants attempted to say aloud the answers to the following questions: What did you just do? What did you find? What do you think about it? Why did you do what you did? The general idea was to identify the mental processes used by the informants to solve problems within the game's environment. The researcher was present during all sessions to prompt the informants to continue to talk aloud and to take field observations. Informal debriefing interviews occurred during the sessions and at the conclusion of the study. The most rich data was related to the problem solving procedures used by the informants to progress through the program. Initial analysis related to *Myst* locations. The second layer described what was happening at the time (strategies, feelings, etc.). The final layer related to novice and expert problem solving skills.

Results/Conclusion

Both informants progressed from novice to skilled *Myst* problem solvers during the study. More importantly the two informants enjoyed the experience and this enjoyment kept them coming back to use *Myst*. This enthusiasm enhanced their problem solving learning experience. Both players solved one of the key problems and got the space ship working. Being able to identify problem constraints is challenging, especially in *Myst*, but it is essential to problem solving. Problem constraints included the key *Myst* locations needed to start the space ship. Both players used many novice and expert problem solving strategies.

As the learners used the multimedia game, they greatly increased their domain-specific knowledge. When activating the space ship, both informants learned how to move through the island, discovered what the marker switches did (activated a light on the map hanging in the library) and learned how to acquire needed knowledge in the library. The importance of domain-specific knowledge was seen in the difference between the two informants approach to powering up the ship. The second informant, with previous electrical experience, demonstrated expert behaviors when he moved efficiently between the generator control room and the circuit breaker towers to get power to the space ship. Once he verified that both gauges had actually worked at the beginning and saw the circuit breaker towers, he efficiently got the space ship powered.

Data organization was an evolving process. During the first session, both informants just wandered around the island. Every detail was separate. After a couple sessions, information was beginning to be chunked and grouped together as either "potentially important" or "just nice to have." Another interesting example of the increased organization of knowledge is related to the informants' journals. During the final interview, the first informant mentioned that she would take higher quality notes if she ever played a sequel to *Myst*. She felt that she would now know what was or was not important.

Experts move from the problem to the solution. This behavior decreases the probability that they will get frustrated and stop working toward the solution. Another related idea is that experts are more likely to set, and meet, subgoals which move them closer to the ultimate solution. Subgoals were set by both players and they usually stopped the current session when they were met. For example, both players stopped the session when the space ship door opened. Within an hour of the beginning of the next session, they had the space ship running.

Informants were clearly developing skills as problem solvers in the *Myst* environment. A study like this provides little demonstration of generalization, but the informants volunteered changes to their own problem solving style and skills. Specifically, they mentioned that note taking is a good way to remember important information and indicated that the next time they played *Myst*, or were in a similar situation, they would take more notes from the start. Additionally, details became more important. They learned to distinguish between "important" details and "decorative" details. A final conclusion was that the informants may have learned the value of the systematic elimination of options when problem solving. Random guessing was unproductive; it lead to frustration. When armed with even a minimal clue, the process of solving a problem was much more enjoyable and efficient. The prospects for generalization of problem solving skills obtained in the *Myst* environment should be enhanced if the game is played in an educational context. The teacher can help the students make connections between strategies learned and their application in other situations.

1 Introduction

Research for use of the Web as a teaching platform has been done. [1] [2]The advantage of Web is that client computer independent of kinds of computer. In the Japanese technical college, after students learn the theory and they becomes parts of their technology via experiment after students learn the theory in the lesson. But by means of students laboratory work require much equipment, time and cost nowadays laboratory works are generally done on computers. Computer simulation is a valid method to verify behavior of system, to check truth of design and so on. We have some commercial computer simulation software so called CAD. But we have to spend much time to learn how to operate them well. Because they are not educational tools.

CAI systems using CAD have been reported by Kurose [3], Matsunaga[4]. Kurose has reported a CAI system for learning free curve and free curved surface. The issue of this system is that learning topics are limited, equations and program of free curve and free curved surface are given then students can not make any computer programs to check behavior of different equations and students deal with different equations on this CAI system. In short students does not independently learn the 3D curve or surface. Matsunaga's report focused the student model. Furthermore his system doesn't support Network and has only character base user interface.

Engineering education in higher education have to offer the students integrated educational environment which combines hyper text book, simulation software tool and high flexibility.

In this paper we describe a design and implementation of integrated LSI design educational system. Furthermore we discuss the learning environment which focus designing in technology education.

2 System Configuration

2.1 Specification of System

Designing of LSI is generally carried out by Fig.1 shown procedure. This system needs as follows functions.

1. dealing with files which are created by learners
2. Editing and Compile
3. Simulation for checking program
4. Output circuit diagram and Synthesis logic circuit
5. Net list for burning FPGA(Field Programmabl Gate Array, Consumer can customize IC)
6. Hyper text book
7. Online manual and help
8. Linkage others Web Site
9. Direct manipulation user interface

One of authors will apply this system to his class. The contents of hyper text book is combinational logical circuits, sequential logical circuits and small educationa computer.

2.2 Configuration of system

We have various software tools to design LSI, free software or commercial software. We adopted PARTHENO made in NTT Japan because as PARTHENON works o UNIX, server client system easily is built. In the system PARTHENON works behind Web Server on UNIX Learners access the PARTHENON via Web browser an cgi. Users files accounting is carried out user id and password. Fig.2 shows system configuration.

Handling files, create, remove, list and so on is carrie out by executing cgi program which issues UNIX command with clicking buttons of Web browser. User ca edit program on input window of Web browser. Som parameters needed in simulation are transferred via cgi Output of circuits diagram comes up browser from converting ps file format to Web browser format. Cgi programs are created with UNIX shell scripts and Perl programs.

BEST COPY AVAILABLE

2.3 User interface

Learning environment offers GUI on Web browser to users. User can edit a HDL program in window of browser, editing means removing, appending or copying character strings. File accounting, New file, Open file, SaveAs etc are carried out by choosing a menu from pull down menu. Programs by HDL can be compiled by clicking button and analyzing error message routine point out the correspond statement. Time chart comes up windows in simulation, of course we set initial values of each register, flip flop and various variables. PARTHENON has been developed in NTT Japan. We can get much information about PARTHENON from NTT Web site. Furthermore a few universities have Web sites for teaching material using PARTHENON. Then this system has link page for the Web sites. Designing of LSI should be realized as a hardware. Then this system has link page to producers of FPGA in order to obtain much information of FPGA. Because system should navigate user valuable Web sites.

3 Conclusion

We have described architecture of IESDL(Integrated Environment Designing of LSI) as a CAI system. We can say that technology education field demands like this integrated learning environment because this system offers hyper learning environment to users. In short this system does not simply combine text book, reference, software tool but they are integrated. In next academic year we will apply this system to class in order to evaluate and improve the system.

Abstract: In order to improve communicative competence, second language learners need to develop intelligible pronunciation. This paper describes a multimedia computer program designed to teach pronunciation to students of English As A Second Language. The program includes video of native speakers pronouncing individual sounds, words and sentences. The learner is then able to imitate the mouth position as well as the sound of the speaker. The program provides opportunity for practice and includes material designed to keep the learner interested while studying.

Introduction

Students of English As A Second Language (ESL) are often highly motivated to improve their listening and speaking skills in order to communicate effectively. However, poor pronunciation skills, especially in the case of adult language learners, hinder their ability to communicate. A large number of teaching materials have been developed to improve the listening and pronunciation skills of ESL students. These materials have changed with the progress of media such as cassette tapes, video tapes, CDs, laser disks and computers.

ESL students cannot expect to greatly improve their pronunciation simply by spending a few hours a week in a pronunciation or oral skills class. Materials are needed that allow students to work individually on their pronunciation skills in a language lab. These materials can be used on their own or as a supplement to a class.

In order to help ESL students improve their pronunciation skills, one must consider three factors – imitation, repetition, and interest. First, imitation is essential in acquiring intelligible pronunciation. Each sound in the English language has a specific articulation involving movement of various parts of the mouth. Students learn to pronounce sounds accurately when they are able to model placement and movement of the lips, tongue etc. Next, repetition is essential. Students may be taught to correctly position their mouth to produce a target sound; however, only through practice can students learn to produce that sound as part of words and sentences. Finally, materials must be interesting and varied. If the materials are boring, the students might not use them.

With this in mind, we will now discuss different media of language instruction. First, cassette tapes are very convenient for learners. Because they are inexpensive and easy to carry, they are widely used. However, though cassettes allow students to hear correct pronunciation, they do not show the movement of lips and tongue. Moreover, it is difficult for students to repeat parts of the tape should they need more practice on a certain section. Second, CDs are similar to cassettes except that it is easier to repeat sections on a CD. Next, the video cassette is superior to the cassette tape in that students can see the movement of the mouth. However, it is also troublesome to repeat sections and is inferior to the cassette and CD in portability. The laser disk is currently an excellent medium for studying and teaching English pronunciation as it enables students to access and repeat any parts that they wish. In addition they can see and imitate the native speaker's lip movements. As we can control laser disks with a computer easily, we are able to design interactive teaching materials for this medium. However, because laser disks are less popular than other equipment, not many students have access to them. Finally we would like to focus on the computer. Recently the price of personal computers has gone down and the performance has risen considerably. Most personal computers have CD-ROM capability with speed more than four times that of a music CD and which can play MPEG and Windows AVI files smoothly. Moreover, as we can buy a CD-ROM writer for less than $800, we can make teaching materials easily with multimedia.

Description

Pronunciation Power has four main chapters – vowels, consonants, stress and rhythm, and intonation -- which each contain several lessons. Each lesson has three main sections – an explanation of the target pronunciation point, a model performance with opportunity to practice, and a quiz. First, in the explanation, a teacher explains and demonstrates how students should shape their lips and where they should place their tongue in order to make the target sounds. Students can listen to the explanation as often as they wish. Second, in the model performance and practice section, the teacher pronounces at least ten words and sentences. The learners see a movie of the teacher pronouncing the words and sentences and imitate the teacher. Students can select words that they wish to hear and say again. The individual learners have the opportunity to focus on the words that are most difficult for them. Finally, in the quiz section, students cannot see the movie of the teacher; they only hear the quiz sentences. Take the "th" sound for example: The computer has a list of words containing the "th" sound and similar words containing the "s" sound. Ten words are selected at random. The students then hear a native speaker say a sentence containing the quiz word. They must decide if the word they heard was a "th" word or a "s" word. Because the sentences are chosen at random, the student cannot memorize the correct answers – they will be different each time. The computer points out the words that the learners missed and they can practice those words again.

We are developing a fourth section for each lesson – model dialogues. Students will hear a dialogue between two people using words containing target sounds. They can listen to and repeat the sentences and target words in the dialogue. We hope that this section will help learners integrate target pronunciation into their speech outside class.

We plan to add some other functions to our program. Students will speak into microphones and the computer will judge the accuracy of their pronunciation. We also plan to record students' learning histories and analyze the characteristics of individual students and of all students.

Pronunciation Power addresses the three considerations mentioned earlier in this paper – imitation, repetition, and interest. When using this program, students see a movie of the teacher and other native speakers. Therefore the learners can imitate mouth position as well as the sound of a native speaker. Pronunciation Power gives ample opportunity for repetition and practice. Individual students can specifically focus on areas in which they need work. This program will enable students to develop not only their pronunciation ability but also their listening comprehension. Listening to a variety of native speakers with the option of replaying each passage will help the learners improve their listening skills. The quiz sections (which generate new quizzes each time they are replayed) and the dialogue sections make learning fun and ensure that students will go back to the program again and again.

Though our Pronunciation Power project is not yet finished, we believe that the current version is also beneficial for ESL students. In order to demonstrate this, we plan to test Pronunciation Power in ESL classes. Student and teacher surveys will allow us to make positive changes in our project in order that Pronunciation Power develops into a useful and interesting tool for language learners.

The Effects of a Spatial Map and a Conceptual Map on Navigation and Learning in Hypertext

Sharon McDonald and Rosemary J. Stevenson
Human Communication Research Centre
Department of Psychology
University of Durham
United Kingdom

Sharon.McDonald@Durham.ac.uk
R.J.Stevenson@Durham.ac.uk

Abstract: This study shows a dissociation between navigation and learning in hypertext as a function of navigation/learning aid. Subjects used either a spatial map or a conceptual map and were asked to read a hypertext document, after which measures of navigation and learning were taken. The results showed that navigation was best with a spatial map while learning was best with a conceptual map. Subjects with no aid also navigated poorly, but their learning was better than that of the spatial map subjects.

Introduction

Spatial maps are often used as navigational aids in hypertext. However, research has shown that while spatial maps can facilitate navigation (McDonald and Stevenson, 1996) they do not facilitate learning (Wenger and Payne, 1994). One possible reason for this, is that spatial maps only depict the structural layout of the document. That is, they only show which nodes are related, they say nothing about the nature of the relationship, or why it exists. Thus, although such aids may assist users in their search for information they are unlikely to facilitate conceptual understanding, and it is conceptual understanding that underlies effective learning. What seems to be needed, therefore, is an aid that facilitates conceptual understanding of the text. We therefore constructed such an aid, which we called a conceptual map. In contrast to a spatial map, a conceptual map identifies the key concepts in the text and specifies the relations between them. Our study, examined the effects of a spatial map and a conceptual map on navigation and learning in hypertext. Subjects were instructed to read the hypertext document. They then searched for ten target nodes, the time it took to locate each node and the number of additional nodes opened over and above the minimum necessary to locate each target node was recorded. Subjects then answered forty questions about the text. Half of the questions tapped memory for factual information the remaining questions required a deeper understanding of the text. One week later subjects competed a retention test.

Results

For the navigation measures, statistical analysis showed that performance was best with the spatial map, next best with the conceptual map, and worst with a pure hypertext. The above order held for both the time it took to locate the ten target nodes and the accuracy of the subjects' chosen route through the document.

As regards learning, statistical analysis showed that for the factual questions, performance was better at acquisition than at retention. In addition, overall performance was comparable with the conceptual map and the spatial map which both produced better performance than a pure hypertext. However, navigation/learning aid interacted with time of testing. At acquisition, spatial map and conceptual map subjects performed comparably and were both better than hypertext only subjects. At retention, conceptual map subjects performed better than both spatial map and hypertext only subjects, who performed equally well. This interaction occurred as a result of the poor retention of the spatial map subjects. For the main ideas questions, performance was better at acquisition than at retention, performance was best with the conceptual map, next best with basic hypertext, and worst with the spatial map. There was also an interaction between test phase and aid, which occurred as a result of the poor retention of spatial map subjects, who demonstrated quite dramatic forgetting across the two test phases.

Discussion

The results showed that navigation was best with a spatial map while learning was best with a conceptual map. Subjects with no aid also navigated poorly, but their learning was better than that of the spatial map subjects. The spatial map and hypertext only results for navigation are consistent with previous findings (e.g. McDonald and Stevenson, 1996). The observation that a conceptual map also facilitates navigation relative to basic hypertext is most likely due to the fact that spatial information and conceptual information overlap.

As regards the learning of facts the results show that a spatial map and a conceptual map produced comparable learning immediately after acquisition, but after a week's delay, spatial map subjects showed poor retention compared to conceptual map subjects. These results support the idea that a spatial map helps subjects construct a superficial structural representation of the text that is useful for retrieving factual information but that decays very quickly. With the main ideas questions, the conceptual map subjects outperformed the spatial map subjects at both retention intervals. This result also supports the idea that a spatial map leads to the construction of a superficial representation of the text. It also supports the idea that a conceptual map facilitates the construction of a mental model (Johnson-Laird, 1983) of the information in the text. A situation model encodes the relationships between concepts, including concepts already stored in the learner's long term knowledge store, and such an integrated representation supports the long term retention of facts and ideas.

The performance of subjects in the hypertext only condition on the factual questions was poorer than with either aid on immediate testing, and poorer than with the conceptual map after a delay. With main ideas questions, performance at both test phases was better than with a spatial map but poorer than with a conceptual map. These results suggest that pure discovery learning with hypertext favours conceptual understanding at the expense of the acquisition of new facts, although even conceptual learning is not as good as with a conceptual map. This suggestion is consistent with the idea that pure discovery learning in hypertext is time-consuming, and further indicates that facts are more likely to suffer than ideas.

In summary, these results favour the use of a spatial map in navigation and information retrieval tasks, and a conceptual map in learning tasks. Basic hypertext also encourages learning, but the time spent navigating through the document may delay its beneficial effects, particularly when learning facts, and this may deter all but the most highly motivated learner. By contrast, the constraints imposed on navigation by a conceptual map not only reduce the time spent exploring the document but also significantly enhance learning.

Evaluation of a Multimedia Program Designed to Engage Students in Scientific Inquiry

Steven McGee, Ph.D.
NASA Classroom of the Future
Wheeling Jesuit University
United States
mcgee@cotf.edu

Abstract: Multimedia software that is intended to support science education reform must be designed so that teachers can successfully adapt it to their local circumstances. This short paper describes efforts at the NASA Classroom of the Future to develop techniques for evaluating the extent to which teachers can successfully adapt its multimedia software.

Introduction

Over the last century, science educators have tried repeatedly to reform science education. From decade to decade the goal has been the same: to help students engage in scientific inquiry and cease being passive receptors of information. In every era of reform, there have been pilot projects that have successfully engaged students in scientific inquiry. In those pilot projects, students learned more and developed healthier attitudes toward science than did students in traditional science classrooms [Shymansky, Kyle, & Alport, 1983]. However, those projects have not become the norm in spite of their promise. Actual classroom practice has remained intractable. Researchers have observed that despite outward appearances, what actually goes on in today's science classrooms remains strikingly similar to the rote practices of the nineteenth century [Bybee & DeBoer, 1994]. Why has it been difficult to extend science education reform beyond the successes of a handful of pilot projects?

According to Cuban [1993], reform efforts often fail to sustain at the classroom level because they largely ignore the inevitable fact that the reformed curricula provided to teachers must be adapted. In their efforts to accommodate the often conflicting demands of many constituencies such as school boards, administrators, parents, and students, teachers cannot use all instructional techniques and materials exactly as intended. Real-world constraints necessarily factor into how teachers implement reform in their classrooms. Teachers are forced to become instructional designers, making decisions about what features of the reform to adapt and what features to preserve. However, if teachers make the wrong adaptations, if they overlook or distort the critical elements of the innovation, not only will students fail to engage in scientific inquiry, but the entire reform movement itself will be judged by the failed implementations. Therefore, it is essential for multimedia designers to investigate how teachers can successfully adapt the software for use in their classrooms.

This paper reports on preliminary results from a pilot evaluation of the *Astronomy Village* multimedia program developed at the NASA Classroom of the Future (COTF) program. *Astronomy Village* presents a virtual mountain-top observatory interface from which students investigate contemporary problems in astronomy [see Pompea & Blurton, 1995 for a description]. After selecting one of ten investigation pathways, students are guided by talking, virtual mentors through the steps of scientific research: background research, data collection, data analysis, data interpretation and presentation of results. The software is intended to help teachers support students at engaging in scientific inquiry. The goal of the evaluation efforts being conducted by the author is to understand the variety of ways that classroom teachers can adapt *Astronomy Village* to engage students in scientific inquiry. For his research on *Astronomy Village*, the author has adopted "academic tasks" as a theoretical perspective for investigating the intersection between teaching and learning [Doyle 1983]. An academic task is defined by the goals that students are expected to accomplish, the resources that are available to students while they are pursuing the task goals, and the operations that students can use in manipulating the resources to accomplish the task goals. Teachers will be able to successfully adapt *Astronomy Village* if they can design academic tasks in which students use the software as a task resource to achieve the task goal while employing operations that mirror scientific inquiry. In order to investigate the ways in which teachers can adapt *Astronomy Village*, it is necessary to develop techniques for determining the extent to which students achieve a task goal and the extent to which the students' task operations reflect scientific inquiry.

Evaluation

Thirteen students from the freshman class of a local girls academy served as the pilot study population. The students came to the COTF test facility in lieu of their science class every day during a four-week period (April-May, 1996). The unit that involved the use of the *Astronomy Village* was co-taught by the author and the students' classroom teacher. The academic task goal that the teachers defined for this evaluation was that students conduct each and every activity that the virtual mentor suggested for each of the phases of scientific research. As part of that task goal, students developed an activity summary for each activity in the LogBook provided by the software. The activity summary consisted of a brief description of the activity, a statement of how the activity related to the main research question, and any new questions that arose from the activity. Thus, the activity summaries served as a record of what students were able to accomplish.

Conclusions

The overall evaluation will investigate both students' ability to accomplish the *Astronomy Village* academic task goals and the extent to which the operations that students used mirrored the process of scientific inquiry. However, the data analysis for this short paper focuses on techniques for measuring the extent to which students accomplished the academic task goals. The number of activity summaries that students developed was divided by the number of activities that the mentor suggested in order to determine the task completion rate. The task completion rate can be used as a measurement technique for determining how closely students achieve an academic task goal. The average task completion rate for this study was 42%. This value indicates that over the four-week period, students completed less than half of the activities that the mentor suggested. An analysis of the task completion rate within each phase of research (i.e., background research - 55%, data collection - 75%, data analysis - 35%, data interpretation - 20%, and presentation - 27%) revealed that the task completion rate was much lower during later phases of research. Based on the poor performance of the students, the *Astronomy Village* academic task structure is being modified to improve students' ability to accomplish the task goal. For example, students should be given deadlines for each phase of research so that they will have sufficient time to complete later phases of research. The task completion rate is only one technique that can be used to evaluate the ways in which the software and/or task goals need to be modified. Subsequent analyses will help identify techniques for measuring the extent to which the task operations mirror the process of scientific inquiry.

Abstract: This paper describes the specification and architecture of a remote teaching system developed in the COPERNICUS Project "Learning and Educational Access using Remote Networks - Enabling the Disabled" (LEARN-ED). It briefly characterises a major part of this system - universal inter-application network communication facility - that is currently used as a vehicle for controlling the presentation of the lecture slides on remote students' machines and locally. Our system is available for all the popular platforms (MS Windows, MacOS, UNIX) as well as for a special one (KA9Q).

1 Introduction

Development of a suitable method for remote teaching was a key task in the LEARN-ED project aimed at finding ways of improving the access to University or Higher Education studies for students with disabilities. Nevertheless our method can be employed by able bodied people as well, because its usability by handicapped persons is mostly the matter of terminal adaptations. The project itself dealt with the problem how telecommunications technology can be used to enable teaching activities and information to be available to students, even when the students are not physically at the site of the teaching activity and information. To support remote education the consortium dealt with both access to persistent information and access to live activities. This paper is focused on the second type of activities.

2 Functional Specification

The requirements involve relaying events to another location on campus, using the campus LAN, but also to an off-campus location, using ISDN, PSTN, or radio links. The core events of interest are the teaching events, when common information being presented or discussed should be available to the remote student. In addition, the student should be able to participate in the discussion by receiving and presenting audio, live text chat, and, if possible, video. The principle functional components of the required service are:

- Audio conferencing between each remote student and the participants in the same venue as the event
- Video conferencing between each remote student and the participants in the same venue as the event
- Text conference abilities to allow specific detailed data to be exchanged (e.g. e-mail or URL addresses)
- Whiteboard facilities to allow all participants to view and annotate commonly visible documents
- Teaching material display to all local and remote participants (the timing and sequence of material to be displayed should be under the control of the director of the teaching event, e.g. the lecturer or the tutorial leader).

3 Technical Specification

The LEARN-ED remote teaching system functions within an Internet Protocol (IP) transport infrastructure, the most prevalent infrastructure technology at universities. The services are intended to be accessed by individual students using desktop personal computers or workstations. The hardware requirements are relatively low to keep the costs of the equipment to realistic levels. All commonly used platforms (MS Windows, MacOS, UNIX) are supported.

3.1 Conferencing Service

The functional requirements for video, audio, and text chatting facilities will need to be provided over low bandwidth links. Some systems have been developed to provide these functions across TCP/IP Internet links. This is attractive because the same network technologies could be used for the information and the conferencing services. The *CU-SeeMe* videoconferencing system is available for both Windows and Macintosh environments. On UNIX systems the *vat* audio conferencing and the *nv* video conferencing system can be used.

3.2 Information Distribution Service

One of the basic requirements for this remote teaching system is the ability to display the teaching material to both local and remote participants. We have chosen presentation of the teaching material in the form of HTML pages, mainly because of platform-independence, widespread acceptance, and good network bandwidth utilisation in comparison with the "traditional" method of sending the material as a video image.

Netscape Navigator has been chosen to display the teaching material as it is possible to manage this browser using its Application Programming Interface (API); via OLE or DDE under MS Windows, via AppleEvents mechanism under MacOS, and via X Window System facilities under UNIX. We have developed a system for generating and relaying such API messages over the TCP/IP network, so the lecturer can instruct the students' Netscapes to display the chosen slide.

3.2.1 Inter-Application Communication Facility Architecture

At last we shortly describe the architecture of this facility. As stated above, the system allows the platform specific API message to be relayed over a TCP/IP communication infrastructure. Basically there are these three types of components within the system:

- Controllers
- Daemons
- Controlled applications

A *controller* generates (on behalf of the user) API messages for the controlled applications. It sends them to the *daemon* running on the same machine as the controller. The daemon relays them to the daemons on the remote machines. Each of them relays the message to the appropriate application (*controlled application*). The success or failure is reported (via daemons) to the controller.

Messages sent from the controller and relayed by the daemon are platform-specific messages (DDE, AppleEvent messages and shell commands for the MS Windows, MacOS and UNIX platforms, respectively) encoded as text. The links between daemons are TCP links. The format of the messages is uniform, so daemons for all supported platforms are interoperable. As a rule, each machine runs one daemon. It is possible to run more controllers together with more controlled applications on the same machine.

Conceptually, the daemon is a simple component. It just relays messages and does not translate them between formats required for each platform. It is the responsibility of individual controllers to know which operating system is running on each remote host and to send suitable messages. Each remote machine informs the controller of its type when a connection is established. This strategy supports flexibility of the system as the daemons are universal and need not be modified when new controllers and applications are employed.

Abstract: We have developed a software package to promote a resource based approach to learning whereby individual subject areas are not considered as the topic of a single "closed book" approach to CAL but are studied by electronically collating via hypertext, as many relevant resource files as are available to the developer. These would include text, pictures, help files, video, sound and animation. It is exploitation of these resources and their constant updating which should make CAL unique as a teaching medium.

In the United Kingdom, the desire to increase the amount of technology based teaching in higher education has been reflected in the large amount of Government funding dispensed through projects such as the Information Technology Training Initiative (ITTI) and the Teaching and Learning Technology Programme (TLTP). While these initiatives have had some success in producing quality material, the teacher with an interest in producing CAL faces several obstacles. One is that the authoring tools available today, require extensive commitment of the teacher's time and usually skilled support (programming skills, educational technologists, graphic designers etc.) to produce quality material (see Laurillard, 1993)

The second problem arises when the first is overcome, and that is that many of the packages represent a "closed box" approach to the presentation of information, ignoring the needs of the host teacher to include their own knowledge and teaching material within the CAL package. The production of these packages has been patterned on the publishing of a book. Teaching methods have traditionally used books and lectures as the cornerstones of information transfer. With the introduction of CAL material and its interactive delivery mechanism, the production of "closed box" material is failing to capitalise on its interactivity and its ability to present the very latest information at the click of a button. Without some means of adding their own input to such a form of learning it is hardly surprising that a beginner in CAL or a sceptical academic may feel:

a) The material is "not quite right" for their course.
b) Distanced from the learning process.
c) That the package will rapidly become obsolete unless upgraded by its authors.

In summary, such CAL packages look beautiful, but are ring fenced by the fact that they cannot be changed or updated, annotated or integrated into a teaching strategy. As a book, it may well be recommended by the local staff, because even if it was considered weak in certain areas those areas would be addressed by local staff via their own teaching methods. The equivalent task with CAL would be to add new software content, and while a subject expert may be eager to update their work (the "second edition" analogy in the context of book publishing) the team of people involved with the project may be otherwise engaged or at worse disbanded.

There is a thus a need to develop a method by which teachers with basic computer skills can collate those information resources best suited to CAL into a single package which can be easily extended and updated. Chief amongst this material would be text and pictures but the former can be improved via a hypertext structure whilst the latter can be "active" pictures which lead to further information. Those resources best suited to CAL would of course be video, sound and animation. It is these resources and their exploitation in interactive teaching which should make CAL unique as a teaching medium. Such a process has been begun by the very elegant "Microcosm" software developed in the UK by Hall et al (1). However such software is expensive and still demands significant computer skills to be used successfully.

We have developed a Windows based program which functions by providing a simple text based outline of the topic under discussion with the possibility of including multiple hypertext links to the resource material. Thus a single word or phrase activates the material (for example a video file) or alternatively presents a menu of ALL the resources relevant to that particular topic e.g. graphics, new text, video clips etc. Such resources are loaded via their parent application e.g. a resource which is a spreadsheet file loads the parent program which then displays the spreadsheet. Such an approach extends the teaching methods a teacher might already use (for example with printed versions of a spreadsheet) by allowing the student to interact with the material. Any such modifications could be saved locally by the student as their own additional material but assuming the original teaching material was delivered over a network, the appropriate access authority would prevent the original material being altered. This approach demands only that the developer know their list of resources and can link them to words or phrases, and enables the regular addition of new resources into the package. These resources could be complete software packages (e.g. the user loads a simulator) or simply resources such as additional text documents, spreadsheets, new web sites etc. This should help to remove the obsolescence factor built into a closed box package. In addition, the selection of quality student essays by the teacher for subsequent use as a resource should encourage new students to contribute to their own learning by developing/extending such material. It will encourage staff with little or no authoring skills to assemble basic resource packs which students can personalise, extend and own.

As an example of the use of our program our medical students were invited to produce three CAL packages as part of a Special Study Module on "Designing CAL". Ten students worked in three sub-groups to produce resource packs covering Microbiology, Hypocalcaemia and the Epidemiology of Infectious Disease. They had access to subject experts and were supervised by experienced CAL designers. Within two weeks they produced a "resource pack" which collated:

a) Pictures scanned from staff slides.
b) X-rays scans (as bitmaps)
c) Text from the WWW
d) Text produced in house from lecture notes etc.
e) Assessment questions produced by our own software program
f) "Powerpoint" presentations.
g) Windows help files constructed in house from material supplied by the students.
h) Video files

These materials are now being edited and will be integrated within the existing CAL material used within the Medical School. It is our experience through workshops and projects such as that described above that teachers who are interested in CAL but unwilling to master a complex authoring package can produce useful material which exploits the inherent strengths of computer assisted learning.

Developing a Laurillardian CAL Design Method

Michelle Montgomery
Department of Computing Science
University of Glasgow
United Kingdom, G12 8QQ
michelle@dcs.gla.ac.uk

Abstract: This paper discusses design methods for CAL and proposes that existing methods are based on out-of-date educational models. The paper suggests a more suitable educational - Laurillard's Conversational Framework - and describes how this was used to help develop a new CAL design method.

At MediaActive '94, Professor Alistair MacFarlane delivered his keynote address entitled "Future Patterns of Teaching and Learning." He stated:

> *"Learning is an interactive and dynamic process, in which imagination drives action in exploring and interacting with an environment"*

Later in the article he stated:

> *"As we move into the next century, technology thus provides us with both a challenge and an opportunity. The challenge is to find out how to construct and deploy highly supportive environments."*

The key phrase being "construct." So how have we traditionally constructed or designed these educational multimedia environments? If any design method is employed, it has been a top down decomposition approach, like early software engineering methods; overall educational aims are identified for the learning package and from these, learning objectives are derived. These objectives are further subdivided until each objective can be directly implemented by a single teaching instruction. This approach implies that teaching causes learning directly, that each piece of the package can achieve one of the learning objectives. This paper suggests that the underlying model of the teaching and learning process in these design methods is not appropriate for higher education and proposes Laurillard's conversational framework as a more suitable model.

Laurillard's conversational framework [Laurillard 1993] takes a different approach to the teaching and learning process; the framework identifies twelve activities that should be performed by the teacher and student for each learning objective. The activities are described as *mathemagenic* activities i.e. activities likely to promote learning. This approach acknowledges that learning is not reliably caused by any single type of teaching event. These activities fall into four categories; Discursive, Adaptive, Interactive and Reflective. The fundamental idea behind the conversational framework is that the teaching and learning process is a dialogue, a conversation in which both the teacher and learner participate. Laurillard states that in the university setting there are two levels of conversation for academic subjects. The first level is at the academic level, a shared vocabulary of words, the level of descriptions e.g. mathematical formulae, technical terms. The second level is at a more personal level, at the level of actions. Laurillard believes that the 12 activities that the framework is made up of, must take place in any learning experience, by traditional methods or by computer, to achieve a given topic goal in an academic subject.

Previously conducted research [Montgomery 1996] used the conversational framework as an evaluation tool for reviewing 13 existing higher education Computer Assisted Learning [CAL] packages in order to establish which activities were commonly supported in current higher education packages, which were not developed with an explicit design method. As stated earlier, Laurillard identified four categories of activity important in the teaching and learning process; Discursive, Adaptive, Interactive and Reflective. In the reviews, each CAL package was checked against the 12 activities in each category in order to find out if that category was supported or not. The

Discursive category results made it clear only one side of a dialogue or discussion was taking place. This indicated despite the potential technology has for replacing the one-to-one tutorial [seen by Laurillard as the ideal teaching and learning scenario], CAL in its design has failed to capture this discursive element. Initially it appeared that the Interactive category of activities was well supported in the exemplars, but it is the type and quality of an interaction that is significant, and on close examination some packages' interaction was questionable. Sims [Sims 1995] indicates the importance of this category:

> *"The planning of* [update] *interactivity is extremely important...the quality and format of media as a component of the* [update] interaction *and feedback will affect the overall effectiveness of the instruction."*

Adaptation seems to be a category that CAL should have scored well on but the results did not confirm this. A long history of tutoring systems based on artificial intelligence principles - Intelligent Tutoring Systems [ITS] have always done this rather well. It is probably down to a developer/designer choosing not to include adaptation due to time constraints rather than the technology not allowing it to happen. In the packages reviewed, Reflection was not generally considered. But one Portuguese language package indicated that it was possible[Montgomery 1996]. So in summary, these packages showed Discursive and Interactive to be common categories to support in current CAL packages designed without an explicit design method, although improvements could be made in the quality of the interaction. However the occasional supported activity suggested that other categories are also possible to support. The results of the reviews were then used as the foundation for formulating a new design method suitable for higher education.

The reviews provided motivation for further exploring the use of an explicit design method based on Laurillard's conversational framework. This paper discusses the development of a design method based on this conversational framework. Although still work in progress, the proposed design method is intended to consist of a set of general guidelines for CAL developers, a recommended development process or lifecycle, a library of exemplar packages providing the developer with good implementations of the Laurillard activities and categories, and an evaluation method for the completed package. The guidelines would suggest performing tasks such as, making important design decisions early in the development process, for example, a developer must decide whether the CAL package is the sole teaching method in the whole teaching and learning process, or is it one of many e.g. does it fit with a lecture and tutorial series? or is it the only teaching method for this topic? The guidelines would also provide the developer with guidance on the consequences of their decisions and the impact they would have on their CAL design. Previous research [Johnson 1996] has shown that providing CAL developers with CAL case libraries helps to educate the developer about the graphical representation of the package, the way the package should operate and how the package should be designed. The use of case libraries was also shown to provide a context for developers to think about their own particular CAL design problem and to provide them with some initial ideas on how to solve their particular problem. The same research indicated that in order to provide adequate support for novice developers, the case libraries must be supplemented with evaluation methods for the developer to evaluate their end CAL design. Consequently the proposed design method will include such an evaluation tool. It is proposed that such a design method based on some explicit model of the teaching and learning process would focus attention on key elements of CAL design. This would avoid the weaknesses found in current CAL designs, as indicated by the previously conducted research, quality of interaction for example, and that effective learning design would become more achievable. The talk will present this work in progress, how several teaching scenarios were used to develop the design method and sketch out how this new design method will be evaluated.

A WWW Client/Server Framework for Educational Software

R. Morelli
Department of Computer Science
Trinity College, Hartford, CT 06106 USA
ralph.morelli@mail.trincoll.edu

Abstract: This paper describes a simple and secure client/server framework suitable for supporting intelligent tutoring systems (ITSs) and other types of interactive help or expert systems. The framework proposed here is particularly well suited for porting existing applications to the WWW, since it divides the application into a Java-based client front end and a non-Java server that could, in principle, run on any platform that supports sockets and HTTP service. A prototype system, PROOFER, which is implemented on a Unix host, illustrates the framework's potential for supporting educational software.

Introduction

As the World Wide Web gains in popularity and influence more and more educators are looking to it as a important medium for the delivery of educational software. There are already a considerable number of educational applications and demonstrations available on the Web with more appearing every day. The development of the Java Programming Language [Gosling et al. 1996], with its promise of executable content, opens up the possibility of new and innovative architectures for educational software. Moreover, the Web's potential for genuine platform independence provides a large incentive for educational software developers to explore Web based connectivity and implementation strategies to support distance learning systems and distributed learning environments. This paper describes a simple and secure client/server framework suitable for supporting intelligent tutoring systems (ITSs) and other types of interactive help or expert systems. A prototype system, PROOFER (http://troy.trincoll.edu/~soar/proofer), which provides help with logic proofs on the WWW, illustrates the framework's potential for supporting educational software.

The Client/Server Model

The client/server model is well understood and programming constructs that support it are available in a number of high level languages, including C, C++ and Java. In a distributed environment, the client and server processes run on different processors that may be located anywhere on the Internet. The socket utility supports dependable two-communication between the interacting processes. Examples of well established client/server applications include the Unix sendmail program for sending and receiving electronic mail, the ftp program for handling file transfers, the telnet application for supporting terminal sessions, and the popular chat applications that support interactive chat on the Internet.

Communication between a client and server takes place over a communication channel known as a *socket*. In order to protect the client's computer against malicious actions, Java applets downloaded over the network are subject to stringent security restrictions. In particular, an applet can only create a socket connection to the computer from which it was itself loaded [Flanagan, 1996].

The PROOFER Service.

PROOFER is a tutorial service available on the WWW (http://troy.trincoll.edu/~soar/proofer) that constructs logic proofs in the propositional calculus. It uses a natural deduction technique of the sort used in many introductory logic courses. Given an argument, PROOFER constructs the following solution, in this case a three step proof of the conclusion *D*.

1. A -> (B & C)
2. A
3. C -> D   / |= D
4. B & C   // 1,2 by modus ponens
5. C   // 4 by simplification
6. D   // 3,5 by modus ponens

PROOFER is implemented on the client/server model. The client process is a Java applet that can be accessed from any HTML document. It provides a simple interface to support interaction with the server process. The client enables a user to type in an argument and submit it to PROOFER, which returns a completed proof. The Java client is event driven and multi-threaded, so that the user can be typing input while the client is receiving a response from the server. The server process is a Soar program that uses pattern matching and inference techniques to construct a valid proof for the argument. It collects each proof step together with its justification and sends the entire proof back to the client, where it is parsed and displayed.

Advantages of the Client/Server Model

Interface vs Expertise. The client/server model provides a secure and dependable communication framework for Internet based educational programs. It is particularly well suitable for applications that require substantial processing power. It also provides a feasible alternative for porting existing applications onto the Web. Rather than rewriting the entire application in Java and downloading it in its entirety, one can implement its interface in Java and leave other portions of it on the server. This is particularly useful for ITS and other AI applications which frequently have a clear separation between interface and expertise. For example, a WWW-based expert system could port its interface to the client side of the model and leave its knowledge base and inference engine on the server. This allows the application developer to have the best of both worlds: a powerful system for developing the interface (Java) and a specialized environment to support its knowledge-based component.

Java and Platform Independence. Using Java and HTML as an environment for the interface provides a number of distinct advantages. First, Java is platform independent -- one version of the software is available to anyone who has a Java compatible browser. Second, Java is a powerful multimedia language, ideal for creating attractive interactive environments. Third, applications written in Java can be distributed through the Web and updates to the application can be made immediately available to all its users at minimal cost. This is an especially useful feature when developing incremental systems. Finally, the browsers that support Java provide excellent security features. This will help reduce concerns that distributing one's educational application in this way will cause problems on the host computer.

Incremental Development. The knowledge and functionality of WWW based applications based on the client/server model can be extended incrementally without having to worry about distributing new versions of the software. This is one of the main benefits of the Web-based client/server framework.

TEACHING THE TUTOR: ACQUIRING DOMAIN KNOWLEDGE THROUGH INTERACTIVE INSTRUCTION

R. Morelli
Department of Computer Science
Trinity College, Hartford, CT 06106 USA
ralph.morelli@mail.trincoll.edu

Abstract: This paper reports on research that addresses the knowledge acquisition problem for intelligent tutoring systems (ITSs) and other knowledge based systems. Soar Instructable Teaching Architecture (SoarITA) is prototype machine learning architecture that learns part of its task domain by taking instructions from an expert.

Introduction

Intelligent Tutoring Systems (ITSs) and other knowledge based systems are characterized by their representation of domain knowledge in a form that can be processed and manipulated by the system. A main bottleneck in developing such systems is the *knowledge acquisition problem* -- the problem of acquiring and encoding the knowledge base. Most ITSs have relied on some form of preprogramming in which the knowledge engineer acquires the information from a domain expert and programs it directly into the system. This approach is labor intensive and requires a skilled programmer. A teacher who wishes to develop an ITS cannot easily input the required knowledge directly. What if there were a way for the domain expert to teach the system the requisite knowledge? This paper describes a prototype architecture for acquiring knowledge automatically through instruction.

An effective knowledge acquisition tool for ITS, must: (1) acquire new domain knowledge efficiently and incorporate it into an existing knowledge base; (2) be accessible to domain experts without requiring the services of a trained programmer; (3) be applicable to a wide variety of different domains; and (4), support acquisition of all types of knowledge used in an ITS. SoarITA (Soar Instructable Teaching Architecture) is a prototype system that satisfies these conditions. SoarITA is written in Soar [Newell, 1990], a production system architecture that incorporates a very general and robust learning mechanism, and is based on previous work in this area by (Huffman and Laird, 1995). Given primitive operators for a task domain, SoarITA uses inductive learning techniques to build up a hierarchy of operators that can be used effectively in ITSs and other knowledge based systems. The ITS framework being used in this project is part of an interactive learning environment (ILE) for elementary symbolic logic [Morelli, Pelton and Dinkins, 1995].

Teaching SoarITA To Do Logic Proofs

SoarITA's present domain is the propositional calculus, and it contains knowledge about inference rules, premises, conclusions, as well as specific productions that support its tutorial interface (e.g., windows, buttons, etc.) and its tutoring operations (e.g., explanations, examples, exercises). SoarITA is being taught how to do logic proofs. The following example illustrates how SoarITA is taught a new a proof of argument 1, which is shown to the right

1	prove (argument1)	How?	**Argument 1**	
1.1	write (premise1).	OK	1. A -> (B & C)	
1.2	write (premise2).	OK	2. A	
1.3	write (conclusion).	OK		|= C
1.4	apply (modus_ponens,1,2)	OK	3. B & C	1,2 MP
1.5	apply (simplification,3)	OK	4. C	3, SIMP
1.6	finished()	OK		

The first instruction in this case is one that is not built into the system. This causes SoarITA to begin accepting instructions on how to perform the new operation. Since each subsequent instruction (1.1-1.6) happens to be a primitive operator, SoarITA executes it (OK). While it is taking instruction it learns new productions that correspond to each step in the instruction sequence. The *finished()* instruction indicates to SoarITA that the user is done defining the new instruction. SoarITA then adds the new operator, *prove (argument1)*, to its list of built-in operators.

The result of this process is the learning of a new production rules that implement the new operator, in this case *prove(argument1)*. The following production proposes the first step of prove(argument1):

```
if the goal is prove (argument1)
and this is step 1 of prove(argument1)
and argument1 has premise1
then propose write (premise1)
and increment the step to 2.
```

On subsequent issuance of *prove(argument1)* SoarITA will fire the learned productions. The context in which the learned productions can be used is fairly broad and general, since the only contextual knowledge they contain is the goal and sequence number. Thus the command *prove(argument1)* can be used by an ITS within the context of other instructions -- e.g., higher level operators -- including within tutorial contexts. For example, SoarITA has also been taught *teach(argument1)* and *walk-through(argument1)*, both of which make use of *prove(argument1)* and are used in tutorial contexts By using learned operators in this way, SoarITA can build up a hierarchy of operations that together constitute the task and tutorial knowledge of an ITS.

Preliminary Results and Future Work

Learning Task and Tutoring Knowledge. Our work so far indicates that it is possible to teach an ITS the appropriate kinds of task and tutoring knowledge, and it does seem feasible that such a system could serve as a basis for an authoring environment for ITSs and other interactive help systems. There is nothing inherent in SoarITA's architecture that would seem to limit its applicability. Any task domain that could be represented as a state space, with operators that perform transitions from one state to another, could be learned in this way. Some examples of suitable domains would include geometry, algebra and computer programming.

The Knowledge Transfer Problem. To what degree does knowledge learned in one situation transfer to another situation? Preliminary results indicate that certain types of transfer are easy -- e.g., every logic proof starts by writing down the premises and conclusion. But that other types are not -- e.g. the inference rules used in one argument don't easily transfer to another. A major question for the ITS context, is whether any useful transfer can be achieved between learning how to do a task and how to teach the task. Results so far indicate that a modest amount of such transfer does occur.

The Initial Knowledge Problem. It is relatively easy to add new primitive operators to an existing domain and to organize these into hierarchies that represent the domain at various levels of abstraction. This kind of flexibility should lead to ITSs that can be more easily adapted to fit students' needs. For students who have difficulty with high-level concepts, low-level operators can be developed, and vice-versa for students who already know the basics of a domain.

Future Work. In addition to extending SoarITA's task domain and incorporating it into a full-fledged ITS, future work will focus on applying learned productions to student-modeling and other ITS problems.

Abstract: A three year project has partnered Baylor College of Medicine, the Harris County Department of Education and twelve Houston-area elementary schools in an effort to achieve school-wide improvements in science, mathematics and technology teaching and learning. As part of the project, different teams of 4–6 teachers from partner schools attend a four-week institute on integrating science, mathematics and technology each summer. Results indicate that participating teachers have improved their skills in the areas of word processing, spread sheet applications, Internet applications and multimedia. These results are supported by evidence of changes in attitudes towards the integration of advanced computer applications with science and mathematics instruction. Several program elements have been identified as most important in influencing teachers' abilities to incorporate advanced technologies into their classrooms: non-threatening environment; opportunity to have sufficient hands-on time at computer; opportunities for self-evaluation; year-round support and creation of large teams of teacher-leaders.

As new technologies become standard tools in American schools, teachers must become confident about integrating different applications across disciplines. As has been noted, technology can support, enhance and, even redefine, the jobs of teachers. However, little research has focused on the impact of technology on teachers or on ways to enhance multiple uses of technologies by teachers [OTA 1995]. These themes are being examined in an ongoing project aimed at providing instruction, hands-on experience and year-round support to teachers in inner city elementary schools in Houston, Texas. The three-year project (Harris County Alliance for Science, Mathematics and Technology Education) has partnered Baylor College of Medicine, the Harris County Department of Education and 12 elementary schools in an effort to achieve school-wide improvements in science, mathematics and technology teaching and learning. Technology goals have focused on helping teachers to become confident users and to learn to incorporate multiple technologies, including multimedia applications and telecommunications, into daily science and mathematics instruction.

Unlike suburban schools, inner city elementary schools sometimes have few instructional resources and offer only limited professional development opportunities for teachers. These problems are exacerbated by the lack of exposure of elementary school teachers to hands-on, discovery-oriented approaches for the teaching of science and mathematics. Hence, teachers in urban schools experience the same insecurity about providing hands-on, problem-based instruction in science, mathematics and technology that is shared by the majority of K–6 teachers, in addition to having to deal with many other complex school and community related issues.

A local needs assessment leading to the creation of the Harris County Alliance project pointed to several barriers that impede the incorporation of multiple technologies and telecommunications into mathematics and science instruction in urban Houston schools. These include:

- teachers' lack of basic skills and knowledge about computers (which must be acquired before teachers can access and apply more advanced applications of technology);
- lack of time for teachers to learn, experiment with and implement new software and hardware;
- insufficient opportunities for teachers to receive inservice training;

- insufficient ongoing support during the school year on technology applications;
- personal negative beliefs by teachers about their own abilities to learn and implement seemingly complex technology applications; and
- misconceptions about levels of expertise required for integrating multimedia into daily instruction.

Project activities were designed to meet these needs by improving teachers' skills, levels of self-confidence and leadership abilities. Each summer, teams of 4-6 teachers from each school attend an intensive one-month summer program focusing on integrating science, mathematics and technology. The program is held at a school with extensive science and technology resources and a direct Internet connection. For four weeks, teachers learn inquiry-based methods for teaching science and mathematics and ways in which diverse technologies can be integrated into those subject areas. Mornings are spent in sessions with visiting scientists and educators, and in science labs (grouped by grade level) under the direction of master teachers.

In the afternoons, teachers work in computer labs, where they are grouped by self-reported ability level (novice, intermediate or advanced). Almost half of the participants are novice users, who have little or no experience with computers. A nurturing learning environment is provided for these teachers by an experienced instructor with 3–4 roving assistants. Before more advanced applications are presented, novice users learn basic word processing and spreadsheet operations. After four weeks, even novices are able to incorporate graphics and text into a single document, access resources on the Internet and use e-mail. They explore programs and learning games on CD-ROM. Each teacher in the program maintains a portfolio that documents progress toward a specific goal. Over 75% of the portfolio goals have dealt with integrating technology applications into science and mathematics teaching and learning.

Considerable effort is devoted to boosting teachers' self-esteem and confidence. The grouping of teachers by experience levels in computing labs has encouraged collaboration. In addition, the recruitment of large teams of teachers from each school has helped develop an *esprit de corps* among participants when they return to their home campuses. Each team is expected to provide at least four inservice sessions to other teachers at their home schools. However, they are supported in this endeavor. Harris County Alliance project staff work with teachers in planning and presenting inservice sessions. In addition, project staff provide year-round support in a variety of areas to teachers at each of the partner schools.

Statistically significant gains were measured among summer program participants in 1995 and 1996 in self-reported abilities to use word processing, spread sheet, Internet and multimedia applications. These results have been supported by evidence of changes in attitudes towards the integration of advanced computer applications with science and mathematics instruction. Most teachers were pleased, and even amazed, by the progress that they had been able to make during four-weeks. A majority of participants expressed excitement about returning to their classrooms and implementing new instructional strategies.

Participants and administrators have identified the following elements of the program as most important in influencing teachers' abilities to incorporate advanced technologies into their classrooms:

- provision of instruction in a non-threatening environment;
- opportunity to have enough individual time at a computer to achieve familiarity and proficiency with a number of applications;
- opportunity for self-evaluation of achievement through the creation of a portfolio;
- demonstration "through doing" of the integration of science lessons with CD-ROM and Internet resources or with the creation of multi-media documents and databases;
- provision of differing levels of instruction to meet the needs of teachers at all skill levels;
- provision of support throughout the year on applications of technology; and
- creation of large cohorts of teacher-leaders, who are able to share ideas and support one another on a daily basis throughout the school year.

Interface Design: Implications for Students with Disabilities

Arthur R. Murphy, Graduate Student
Georgia Institute of Technology
Center for Rehabilitation Technology
490 10th Street
Atlanta, GA 30332-0156
arthur.murphy@arch.gatech.edu

Abstract: Access to education is a universal right. This simple statement of inclusion is part of the legal requirement of the Americans with Disability Act. More fundamentally, this principle of universal access is an essential standard of an advanced civilization. Historically, however, the inclusion of students with disabilities into traditional educational environments has been done poorly. For many years, students with significant disabilities were relegated to separate facilities. Early efforts at inclusion resulted in integrated classrooms, but frequently, separate instruction and media. Today, as the movement toward fully combined classrooms becomes universal, the need for adapted and adaptable media is clear. Despite a compelling need for instructional materials that work well for disabled students, inclusive accommodations are rarely done properly. Just as no thoughtful architect would intentionally design a building to exclude mobility impaired citizens, no thoughtful information designer would want to exclude disabled users.

Despite legal requirements and obvious needs for universal design considerations, exclusionary design is still common. Why? I would suggest that there are several sensible reason for deficient software - programs which work poorly for students with physical or cognitive impairments.

The traditional reason for restrictive software is cost. To move from simple functional programs to comprehensive flexible systems may require extraordinary increases in effort Furthermore, the needs of a _special audience_ are not clear to designers. Indeed, it could be argued that designers are still struggling with interactive software models which work well for a *standard* audience.

Unfortunately, there appears to be no single point of information as to what legal requirements have been specified to meet ADA regulations. There are no extensive references in HCI texts concerning users with disabilities. Some media developers are reluctant to involve people with disabilities in the process of design and testing - fearful that a Pandora's Box of issues will impact the complex process of system creation.

Yet, the ADA advocates _reasonable_ accommodation - not totally comprehensive accommodation. The legislation describes both "rights and responsibilities" of people with disabilities. Implied, is the participation of people with disabilities in the design process.

This paper presents three basic observations to harmonize short term constraints with long term requirements:

- the aging of the population implies a widening continuum of abilities;
- totally comprehensive solutions are unnecessary if extensibility features are included and access to underlying content is provided;
- inclusive designs are essentially good designs which embody a deeper awareness of principles of visibility, obvious affordances, error correction, and clear feedback.

An Aging Population - the "Temporarily Able-Bodied"

As demographic shifts in the population predict a larger percentage of older people, and as the need for adult education (remediation and retraining) continues, the _standard audience_ moves in the direction of diminished ability. Older people have less acute vision, hearing, mobility, reduced short term memory, etc. Overall cognitive function may persist at a full level, but at a slower speed. Control of speed may be a critical area in interactive system design. Ironically, more powerful computers have made extremely fast interaction the norm. Yet, current studies indicate that many cognitive deficits are compensated when speed is controlled by the user (or, is intentionally reduced by an insightful instructor). [c.f. "Scientific American" November 1996 - _Dyslexia_ by Sally E. Shaywitz. The article suggest that speed of presentation of text may be extremely important in dyslexia and several related information access challenges.]

Content vs. Format

This primary principle should be inherent in flexible design. Initial creative development works best when content is divorced from a specific presentation medium. Indeed, as the need for cross platform implementation increases, (as re-mediation of material becomes common), effective design tools are still pencil and paper. Or, for collaborative work, a white board and markers. Although there are sophisticated techniques for sharing sketches in a computer environment, the principle of avoiding pathological reliance on a specific software environment is vital. The developments of basic content, generic interactivity, and early usability questions are often best addressed in an environment where revision is a simple as using an eraser...

As many programmers have discovered, the key to effectiveness is intelligent re-use of robust code. If an effort is made to separate content from format, conversions are done more quickly. Clearly, this separation is the intent of markup languages. However, in much current HTML, the text, formats, and images are too closely intertwined - testimony to seductive temptations to embed meaning within the constraints of a specific syntax. The experience of "hard coding" done by early programmers suggests that short term savings are counterproductive when conversions inevitably occur.

Two advantageous side-effects of separating form and content extend software engineering benefits: the ability to extract ASCII text from all content (enabling countless unforeseen accommodation techniques); the option to use automatic forms of redundancy (e.g. concurrent audio and text of the same content).

Hence, accommodations in interface access are less likely to be a retrofit; they are more apt to be the natural extension of an existing structure. Such accommodations may be made by the creator of the package - they may also be made as "reasonable accommodation" by organizations within the rehabilitation community. (e.g. information in a markup language can be sent to a publishing house for blind students and automatically produced in Braille as needed.)

Such standards combined with an awareness that users of educational software tend to be novice users rather than experts, should inform interface developers. Not in terms of a restrictive constraint, but in terms of conventions for inclusion.

Finally, the essential argument of HCI is that we are still in the formative stage of design. We have the opportunity, by involving an increasingly diverse population, to discover within the design process, valuable and universal structures of information access. Just as education is increasingly moving in the direction of collaborative student work - an appreciation of diverse views and a recognition of synergistic cooperation, designers must appreciate universal design principles in the broadest light to brighten the HCI horizon for all.

Teaching Multimedia Systems Design

Klara Nahrstedt
Computer Science Department
University of Illinois at Urbana-Champaign
e-mail: klara@cs.uiuc.edu

Abstract

"Multimedia Systems Design (MSD)" teaches graduate students principles and practice of large-scale multimedia system design. The biggest challenge to teach students how to design and build multimedia system is the *integration* aspect because multimedia systems integrate various computer science areas such as audio/video processing, operating system concepts, high-speed network protocols, user interfaces, and others. Our approach is to apply concepts and examples from these areas to construct a significant project, such as a *digital distributed VCR system*. The course focus is on a large-scale, long-lived software system of a size requiring group effort. In this paper we therefore address the results of this new course, in particular its implication on students' understanding of multimedia systems.

1 Introduction

We have developed a course *Multimedia Systems Design* which we believe fits into the CS curriculum. It introduces new concepts, services, protocols, algorithms and integration of all of them to design and build future advanced multimedia systems. Furthermore, the focus is on the *application* of principles and concepts, and on learning from a single extended experiment. The learning is directed towards construction of significant long-lived, large-scale multimedia systems within a group, as opposed to construction of throwaway examples by an individual student.

The course has accomplished successfully its goals. The students leave the course with a thorough understanding of various areas in multimedia systems, especially their integration aspect. Furthermore, they learn a tool-rich programming environment for building complex audio-visual systems. More important, they have worked on a project of significant scope, built significant software application, and understand the group nature of systems building.

There are not many multimedia systems courses available currently. There exist several courses which emphasize individual parts of multimedia systems (e.g., [Smi95, Row95]. The major difference we see is in the integration aspect of our course and the choice of the project which stresses the importance of the integration (see web page: nahrstedt.cs.uiuc.edu:5000/pub/cs397mm.html).

2 Discussion of the Course

The course presentation was designed so that the covered material would emphasize the integration aspects of the multimedia systems and would properly map to the project design, implementation and testing stages. The lectured material and the project are approached so that they would not become obsolete; the students would get the knowledge and experience with the newest technology, however, would understand the tradeoff among the design choices if certain technology is not in place. The students would be constantly working towards both the development of a project and overall understanding of the multimedia system issues, which would serve them well in both this course, and later courses. The course includes seven basic assignments as shown in table 1. All assignments are group efforts. There are several components we see in this type of a course, namely (1) learning the state of the art in multimedia systems area, (2) experiments, (3) replication of experiments, and (4) observation and deduction.

BEST COPY AVAILABLE

Segment	*Description*
1. Project Design	Design GUI and process structure
2. Multimedia Functions	'record', 'play' 'rewind', 'fast forward'
3. Multimedia Scheduling	CPU admission and RM scheduler
4. Client/Server Communication	Client/server protocols for audio/video
5. Lip Synchronization	Synchronization structures, and streams
6. User Interface	User-friendly GUI
7. Integration	Integrate client/server communication with GUI

Table 1: Summary of Course Phases

The results from the class taught in Spring 1996 show that the choice of the VCR application had four positive effects: (1) Students knew this application from their homes, hence the functionality of the application and the goals where clear; (2) The students were not forced to complete the design process before they were ready. Their design process consisted of analyzing new features in the context of their existing software, designing appropriate data structures and algorithms, and implementing the features; (3) The completed VCR application allowed the students to become familiar with most of the aspects of digital video and audio processing and communication. Functional details of compression, scheduling and Internet communication taught students not only the individual areas but also the integration aspect when building a complex distributed multimedia application; (4) Experimentation with digital video and audio within their VCR application was a very worthwhile experience. Especially, because they could mostly hear or see how their design performs.

3 Conclusion

I hear and I forget, I see and I remember, I do and I understand. (Chinese Proverb)

Overall, the course had the following principal accomplishments: (1) The student developed a non-trivial multimedia application, consisting of both techniques and developed skills with digital audio and video. (2) The focus on one significant project brings out the point of *integration*, which is so important in distributed multimedia applications; (3) Forcing integration of new features with previous work also demands that attention be paid to design. Of course, building on previous work shows the value of *re-use*. (4) The course is a system course which brings, similarly to operating systems course, together concepts, approaches, algorithms and structures with real implementation and experimentation on real application.

Collaborative Reflective Practice
A Teaching and Learning Architecture for the Internet

Som Naidu, PhD
Distance Education Center
University of Southern Queensland
Toowoomba, 4350, AUSTRALIA
Phone: (076) 31 2040; *Facsimile:* (076) 31 2868
Internet: naidu@usq.edu.au

Abstract: This paper describes the teaching and learning architecture and the results of an evaluation of the first offer of an Internet-based graduate studies program in "open and distance learning" which has been financially supported by the Australian Federal Government, and a global learning initiative from AT&T, and the ICDE. This program is designed to meet the needs of academics and trainers seeking skills in the development of open and distance learning programs. The program is accessible via the Internet and was first offered in 1996. The experiences of the first student intake suggest that the program is successfully meeting an identified need. The program developers describe this program as challenging and clearly trailblazing the push for increasing flexible learning opportunities.

Introduction

Open and distance learning is increasingly becoming a core form of educational activity for instructors in both formal education and work place-based systems. However, many of these practitioners have little or no formal education in open and distance learning techniques. This graduate certificate in open and distance learning is designed to meet the needs of this group of people. Anyone from anywhere around the world with access to the Internet can enroll in the Graduate Certificate if they have an undergraduate degree or equivalent knowledge in the field. The program of study became fully operational in Semester 1 (February) 1997. The technologies and the pedagogical architecture of the program was trialed with a global intake of 25 students from the collaborating institutions in Semester 2, 1996 (July-November).

Instruction Vs Facilitation

There are some fundamental differences between teaching and learning via the Internet as opposed to conventional classroom based processes. Among many other things, the Internet enables written asynchronous communication between participants and within the group. This facility allows for a vastly enhanced teacher-learner engagement and different pedagogical architectures which emphasize facilitation of the learning and study process as opposed to those that emphasize the delivery of subject matter content. The "instructing" teacher expounds, explains, reports, and describes. A lot of this happens in conventional classroom as well as distance education contexts. The "facilitating" teacher on the other hand, functions more like an advisor, coach, guide or mentor who not only presents concepts and organizes the learning environment but also helps learners study, question, reflect on and relate their experiences to others.

The architecture described and evaluated in this paper is a modification of the Kolb Learning Cycle (Kolb, 1984); (http://nexxus.som.cwru.edu/dept/cmost/learn.html). This architecture epitomizes mostly the facilitating role of the teacher in engendering collaborative reflection on practice by learners. Learners access the content on the WWW with a PIN at a secured site at the University of Southern Queensland. This material includes discussion of the concepts and principles including both print and electronic references on them. Learners are required to *study* this material and *reflect* on it. The course content is presented in the form of small chunks of textual information that is hyperlinked and accessible via a set of graphic organizers and also the study chart.

Computer Mediated Communication

Students and instructors in the Program are able to communicate with one another directly (via e-mail) or as part of a group via a computer conferencing software called ABOUT™. This is a Web-based conferencing system which allows easy access to the study materials and the communication channel between and among students. With this system participants are able to send messages to the whole group on matters of common interest to them, as well as to individuals on issues of personal interest.

BEST COPY AVAILABLE

Program Evaluation

Feedback from the first cohort of students and members of the program development team was sought on various aspects of the Program. From the students we sought data on the presentation of the study materials on the Web and on accessing of these materials on the Internet; the uses of computer mediated communication for interacting with participants in the study program; and the use of practice-based "reflection in/on action" as a learning and instructional strategy in a computer supported collaborative learning environment. Students were asked to react to several propositions (about 6 to 8) that were presented to them in the form of statements in relation to each one of the issues we raised with them about this mode of instructional delivery. For each one of these propositions firstly, they were asked to indicate their reactions to it on a three point scale like "yes/no/to some extent", or "not at all/to some extent/very much so". They were then asked to explain their responses in a few sentences. From program staff we sought their thoughts on the advantages of the Internet for teaching and learning, amount of time they spent at the peak of their involvement in the project, the nature of their input in the project, and their preparation for carrying out the tasks.

Student Responses

First, we asked students about the presentation of the study materials on the Web. Most of the students said that this mode of instructional delivery best met their learning need as practitioners. Citing time as a major constraint in their working lives, they claimed that the time, pace and place flexibility of this study program allowed them to combine work with formal study in the discipline. Most of them said they had sufficient skills to search for relevant source materials on the Internet and that the problem was not with skills, but with the availability of time. They all thought there was enough information in the Grad. Program documentation on searching for resources on the Internet and that they were able to locate enough resources for understanding of the content of the courses and completing the assessment requirements of the courses in the program. All of the students thought that the sources on the Internet were often of greater value than those in the textbooks in furthering their understanding of the course content. None of them had any real difficulty with communicating electronically but found composing messages directly onto the computer initially somewhat cumbersome. A lot of the problems with composing messages directly on the screen had to do with the editing facilities of ABOUT conferencing system we are using. For most of the students, being able to express their thoughts directly onto the computer was more a matter of getting used to this mode of communication and interaction among peers, than being able to cope with the technology itself. Everyone claimed that the most useful function served by the use of "collaborative practice-based reflection in/on action" was its critical role in motivating them to interact with others in the course.

Developer Responses

The Graduate Certificate Program Development Team was a large group that comprised people from a number of departments and sections in the University. From the members of the program development team we sought responses and their thoughts on the advantages of the Internet for teaching and learning, amount of time they spent at the peak of their involvement in the project, and nature of their input in the project and preparation for carrying out the tasks. The program development staff thought that the presentation of content via the Web and the Internet was valuable, for it enabled lecturers to introduce desirable changes to the content without much hassle. They also thought that Internet-based teaching and learning was tremendously valuable for lecturers as it enabled much richer communication and interaction among participants which is foremost, asynchronous and as such more suitable and attractive for adult learners. Much of the advantages of this mode of learning proclaimed for the students had to do with ease of communication with peers, instructors and access to a richer and more set of all types of resources, as well as management of their registration process. Respondents saw many obvious advantages of the Internet-based teaching and learning environment for the support of students and their learning. These advantages had to do with rapid response to student queries, ability to follow-up actions being taken to address student concerns and queries and a consequent reduction in time wasted at waiting by the telephone for both parties.

Multimedia in the Science Lab

Norma Nocente
Department of Secondary Education
Faculty of Education
University of Alberta
Edmonton, Alberta, Canada
Norma.Nocente@ualberta.ca

Abstract: Many science labs require that students make observations or draw diagrams of what they have seen. Multimedia tools in the science classroom can now help students capture what they see and then revisit it for further analysis. Multimedia can also be used by students to integrate their laboratory work with the content material present in class. This paper provides examples of how students can be more actively engaged in the analysis and synthesis component of the science lab.

Effective use of computer technology in the classroom has the potential to assist children in developing skills to gather appropriate information, problem-solve, and make informed decisions. Also, thoughtful integration of the technology in a class is an important step toward preparing students for the highly technological world that surrounds them. Despite the obvious benefits we do not see widespread effective use of technology across the curriculum. In science courses teachers often talk about technology but unfortunately do not integrate it into their classes [Forbes, 1995]. Part of the problem may be a lack of funding for hardware and software but even well equipped schools are struggling with technology integration.

This lack of integration even when the resources exist may endure simply because teachers see it as requiring great effort for minimal gain. That is, what are students actually gaining from this computer experience? Teachers have been asked to take on more and more duties because of recent cutbacks in education. It seems impossible for these teachers to now find the time to discover how a computer can be effectively integrated into their class. Therefore assuming teachers know how to use the tools, they need to be given some ideas for effective integration. Science classes and labs in particular, can take advantage of spreadsheets, databases, simulations and multimedia. This paper will focus on examples of multimedia and hypermedia activities for science labs. These examples are practical and make use of the computer's unique capabilities.

Digitized video in the science lab has opened up opportunities for new activities. An affordable piece of hardware that has emerged in the last two years has vast potential for our microscopy labs. The QuickCam® recorder from Connectix will plug into the modem port of a computer and can capture color video at a rate of 30 frames per second or it can take a snap shot picture. With this type of technology in a microscopy lab teachers can start to move away from the simple task of drawing organisms seen under the microscope to activities that require more critical analysis of the specimens. For example, a common biology lab involves the examination of pond water. Students are expected to identify the organisms they see. They often look through the microscope and refer back to an identification chart. A problem with this lab however is that it is difficult to follow organisms as they swim out of the field of view. Capturing video of the specimen would provide students with more time to refer back to their identification charts. In this way students can work collaboratively by pointing out features of the specimen as it is viewed on the screen. Such an activity opens up the identification process to discussion. Students justify their rationale and have an opportunity to oppose another opinion. Certainly if more lab time could be devote to this type of discourse it would encourage more analytical thought than the process of drawing the organisms in the field of view.

Another activity, for the same type of lab, would have the students save video segments or pictures of their specimens along with their results to the file server so that other students can view their work.

BEST COPY AVAILABLE

Again this provides students with the opportunity to discuss and debate findings but it also let's them see organisms that were not present in their own sample. Certain video segments or pictures could be viewed on a large monitor by the whole class. In many ways this process replicates, on a very small scale, the activities of the scientific community.

With the proliferation of CD-ROMs in the school and home, students have become quite familiar with multimedia. CD-ROM encyclopedias, reference materials, and talking books contain pictures, graphics, video, audio, and animation components. Since our students use these materials frequently in the library it seems logical to now have them prepare their own multimedia lab reports. Multimedia lab reports allow the student to represent their knowledge and findings using a wide array of tools. Complex ideas can be represented in various media forms thus allowing the student the capability of expressing his/her explanations in creative ways. Software such as HyperStudio® and Smart Ideas® (a hyperlink, multimedia, concept mapping program) allow students to easily and quickly construct multimedia representations of their own understanding of concepts. The different format provides new opportunities for students who have difficulty expressing their understanding through conventional means such as oral and written reports. The real potential for the use of technology occurs when students use the tools to reconstruct or represent their knowledge [Jonassen, 1996]. For example, as students progress through a unit on the circulatory system they could gradually build a concept map showing the relationship between concepts. Using a tool such as Smart Ideas® or Inspiration® they would be able to incorporate multimedia components, gathered during labs, into their concept map. Therefore the term arteriole might have associated with it a digitized photo of an arteriole cross section.

It simply is not enough for teachers to know how to use the computer technology. To ensure effective integration of technology teachers will need to share examples of successes and failures. They will need concrete examples of integration that are connected to curriculum topics.

Creating a Learning Environment on the WEB: Instructional Design Issues

Solvig Norman, B.A., M.A.

Instructional Designer

Email: solvign@olax.ola.bc.ca

Open Learning Agency, British Columbia Canada

Abstract

Many educators around the world are discovering the potential use of the World Wide Web as a delivery medium, content provider, and subject matter—providing new ways of designing instruction and new challenges. This short presentation will examine instructional design criteria for developing an appropriate learning environment on the World Wide Web. Technological capabilites, new instructional strategies, challenging role of learners and the teachers will all be examined within the context of a high school level course titled *Instructional Technology 11* presently being developed and delivered on the World Wide Web.

The World Wide Web has provided a new "geography" for learners around the world and a challenge for educators to design appropriate "maps" to help guide them through this vast new terrain. Traditional approaches to designing instruction (e.g., behavioral objectivistic approach) need to be revisited and possibly merged with a more constructivistic approach to form a hybrid model suitable for creating a learning environment on the World Wide Web. Some features to consider for a hybrid model include the following:

- examining the capabilities of the technologies (the World Wide Web as an integration of video, audio, print, hypertext linking, multimedia, interactivity etc.),
- considering new instructional strategies (e.g., more applied and collaborative approaches),

BEST COPY AVAILABLE

- examining the role of the learner (e .g., as a creator of content),
- examining the role of the teacher (e.g., as a facilitator),
- different models of assessment (e.g., more applied and authentic assessment).

These features have been implemented within the design and delivery of a high school level World Wide Web based course titled *Information Technology 11*. This course is presently being developed and delivered through the Open Learning Agency in British Columbia, Canada.

Information Technology 11 is designed to encourage students to develop an awareness of the globalization of information and gain mastery of electronic communications concepts. Students taking *Information Technology 11* have an opportunity to complete four modules covering topics such as publishing on the World Wide Web, networking, programming, and multimedia. They have the ability to access the course on the WWW through a password protected system. They work through the content on their own pace, complete a series of hands-on applied activities (learning tasks), and interact with fellow students through an on-line conferencing system. The outcome of the students' work will contribute to the content of the course, thereby providing opportunites for students to be *producers* of content and also *explorers* of content. Students are *facilitated* by an on-line mentor who provides motivation and direction to help them with the learning process through negotiations, monitoring discussions, and project work.

Informational Technology 11 is an example of a course which has *mapped out* some of the new *terrain* using the World Wide Web as a development and delivery model and at the same time adopted a hybrid instructional design model using key features from both the objectivistic and constructivistic approaches.

Designing a Virtual Writing Center for Active Learning: SUNY Empire State College's The Writer's Complex

Susan Oaks

Cathy Copley-Woods
ccopley@sescva.esc.edu

Elaine Handley
ehandley@sescva.esc.edu

Larry Greenberg
lgreenbe@sescva.esc.edu

at
State University of New York, Empire State College, USA

Abstract This paper discusses the design of a web-based virtual writing center intended to promote active learning among adult college students doing guided, independent, distance study. We detail the initial idea behind The Writer's Complex, to reproduce the activities that promote active learning in a site-based writing center, and we discuss the thinking and basic research that contributed to the design. We explain first experiences with the center's use and discuss plans for future development.

Background

SUNY Empire State College serves primarily working adults through guided, independent, distance study. A group of faculty designed The Writer's Complex (http://www.esc.edu/writer.htm) as a virtual building that offers similar services and support on the world wide web as a writing center at a residential college, especially including activities that promote active learning.

Writing Center Design

Students can interact one-to-one, on-line, with a text in hypertext format, a text whose pieces create meaning for the student as the student combines its pieces consciously. As [Lanham 1993] states, "the fixed print surface [on the electronic screen] becomes volatile and interactive" (p. 73), making the student a conscious participant in the reading and creation of a text, a first step toward what [Meizrow 1994] calls "discourse," that interior dialogue created as a result of consciously and critically interacting with a text.

Yet discourse involves more than hypertext links. Some rooms offer interactive exercises designed to get the student to think about samples, get immediate feedback for their answers, and self-assess their knowledge, ideally with some critical awareness. Each interactive exercise offers the option of questioning an outcome or getting more clarification from a tutor through electronic mail, shifting the interaction from student-text to student-tutor. The File Cabinet Room supports the same type of critical awareness by providing informed readers' interpretations of texts

The Writer's Complex also encourages discussion of writing through its Escape Clause conference, which offers students a chance to experience the interactive/collaborative style of learning (in addition to the interactive/individualized style that the student-text and student-tutor relationships provide).

Experiences to Date

The Writer's Complex is a work in progress and has been available as a service and a forum on writing for our students. We have done only informal evaluation of its use up to this point, as we have focused primarily on getting the Complex up and working. Our preliminary data spans twenty-nine weeks, from June 16, 1996, through January 4, 1997.

The Complex is accessed on the average of 1939 times per week. Users access a variety of files, an average of 407 different files each week out of a total of approximately 570. Users have most often accessed information on the concept of academic writing, language and writing skills, and sample academic papers.

A shift occurred in early November through mid-December from greater access of menu pages to greater access of content pages dealing with research writing (e.g., citation formats, best sources to choose for particular research papers, etc.), most likely coinciding with student research papers that were due for the fall term. When usage dropped off sharply in mid-December, users went back to the previous pattern of accessing menu over content pages with more frequency.

Users have tended to access the Complex steadily during the day as opposed to late at night and, although information about days of the week is incomplete at this point, more users tend to access the Complex early in the week (Sunday, Monday, and Tuesday).

More important than numbers of persons accessing the Complex, though, is what happens once users are there. It appears as though users are visiting to receive answers to their writing questions more than to discuss the process of writing or their own specific pieces of writing. Although students have successfully created certain strings of discussion, they have not accessed the Escape Clause conference frequently enough to place it in the top 100 documents accessed by count each week, perhaps due in part to the cumbersome nature of the conferencing option. Student comments and other anecdotal information bear out this finding. Though it has taken some time to get started, student-tutor dialogue has been increasing slowly.

Plans for Future Development

We have been somewhat successful at fostering student-text and student-tutor interaction in The Writer's Complex, yet these modes emphasize the individual writer as he/she moves through the process of writing. We plan on implementing two strategies to encourage more student-student interaction in the future, 1) use of the Complex in conjunction with classwork, and 2) space and context for student discussion as the students use the various rooms--no separation of "teaching" and "talking" space, since the teaching occurs through the talking. In the future, we hope to create a community of writers who read and talk--through writing--about the process of writing and thus become active participants in that process.

HyperClassroom : Networked and Computer-Assisted Learning Environment

Takeshi Oda, Widjaja Sangtoki, Takao Ushiyama and Shigeyoshi Watanabe

Dept. of Communications and Systems,
The University of Electro-Communications, Japan
{oda.widjaja.ushiyama.watanabe}@sw.cas.uec.ac.jp

1 Introduction

Tutorial or instructive support for a student by a teacher is strongly desired in both environments of individual learning and collaborative learning. Although the support gives a student the benefits of good understanding, all of students can not receive it at the best chance of understanding for them, especially in a traditional classroom. We propose the idea of HyperClassroom which is a computer software and assists both of students and teachers in both environments of individual learning and collaborative learning. HyperClassroom includes functions of storing the learning behavior record of any student and provides the best learning environment for the student according to own knowledge state timely and seamlessly.

The major theme of this paper is to propose a system which solves the problem when and how the teacher gives a help to the student who gets into trouble or wishes navigation. We call the system REEL (Replacing Environments and Encouraging Learners). The REEL contains Fuzzy reasoning which chooses the best assistant or collaborators and prepares the student the communication channel.

2 Concept of HyperClassroom

As many computer softwares are used in conventional classroom education, the load of a teacher in a classroom are increasing because the teacher must participate in student's performance and gives suggestions, answers questions or undertakes tasks at any time when the student is in trouble. HyperClassroom serves both of students and staffs (a teacher and a few teaching assistants). The mode of communication is image demonstrated on computer displays (CRT). The communication can be attained via computer network. The general learning style of a student is a HyperText-based individual learning by World Wide Web (WWW) services. Other learning styles such as an individual practice or a collaborative learning are also supported by HyperClassroom. The choice of learning style or determining collaborators is mainly done by a staff.

[Fig.1] shows the detail of HyperClassroom. In the figure, three different learning environments, i.e., practice by Intelligent Tutoring System (ITS), HyperText-based learning and collaborative learning are shown. The student's request to a staff can be attained through communication interface and communication server. Three different interfaces are prepared and each learning behavior is recorded in Practice Log, Reference Log or Communication Log, respectively. In order to build the student model, integrated logger integrates the three logs of the student. Similarity of student's behavior is calculated by the Fuzzy reasoning in REEL which uses the log data. Staffs can monitor the similarity and then have the chance of interruption for replacing learning environment when some student requests staff's help or is in trouble.

3 Prototype and REEL

We have designed the prototype of REEL which serves one hundred undergraduate students at a time and four staffs including a professor in a computer classroom. The subjects of 'Introduction to UNIX' and 'Pascal Programming' are the one semester curriculums. The computer system consists of a file server and networked twenty clusters each of which is composed by one workstation and four X-Window terminals. The file server is a workstation which distributes required teaching materials to the CRT of the student and stores the learning behavior record. The similarity measure we introduced here is making use of Fuzzy reasoning[Sangtoki95, Enrique93]. Before we use the learning behavior record, namely student's referencing page and study time, as data for reasoning, we use them to calculate the *appropriateness degree of study time (ast)* and *common referencing degree (crd)* respectively. And then we use them as the input to the Fuzzy Reasoning Engine after the fuzzification process done, due to the data are crisp ones. At the next step, we apply the Fuzzy rules and generate a fuzzy reasoning result. At last, we defuzzify the result to get a crisp final result.

4 Experimental Results

The prototype excluding the systems of the learning action monitor and the cooperative learning support was already available from the last semester and more than 250 students studied each of two courses in two semesters.

Figure 1: Detail of HyperClassroom

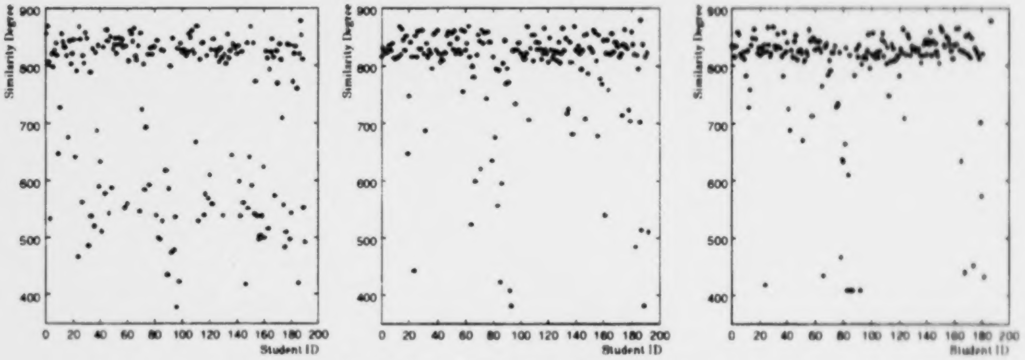

Figure 2: Estimated Result of Similarity Degree

[Fig.2] shows the similarity degree *sd* of almost 200 students in the succeeding three weeks. The topics of each week are E-mail, Netnews and customization, respectively. The *sd* value of most students is between 750 and 900. It means that the student's learning behavior is very similar to each other in every three topics. From the result of similarity degree, the difference of learning behavior between arbitrary pair of students is easily determined.

5 Conclusions

We have proposed the integrated multiple learning environments such as individual learning and cooperative learning and named HyperClassroom. We explained the concept and the fundamental structure of HyperClassroom. Then we introduced the prototype and described REEL which is the system of replacing learning environments and encouraging learners.

The results of measuring the difference of student's behavior from learning behavior records are obtained. From these experiments we found no evident defect of the prototype. Now the prototype only includes the complete versions of two systems in the four fundamental systems. In order to serve students with the best learning environment, we are developing the remained systems.

A Case-based Pharmacy Environment: Cognitive Flexibility + Social Constructivism

Kevin M. Oliver
Department of Instructional Technology
The University of Georgia, USA
koliver@coe.uga.edu

Abstract: A hypermedia, case-based learning environment has been designed to promote cognitive flexibility in college Pharmacy students. Literature suggests such environments promote complex knowledge structures in students with complex epistemic beliefs, but may cause students with simple epistemic beliefs to struggle. This paper suggests and describes the combination of social constructivist approaches with a cognitive flexibility hypermedia environment to promote learning for students with varying epistemic beliefs.

While it has been shown that cognitive flexibility environments promote complex knowledge structuring in students with complex epistemic beliefs, there is evidence that students with simple epistemic beliefs may struggle with the same materials [Jacobson & Spiro 1995]. This paper describes a hypermedia, case-based environment designed at The University of Georgia College of Pharmacy and suggests the combination of social constructivist approaches with this cognitive flexibility environment will promote learning for all students.

With a key objective of pharmacy education being patient problem-solving skills, the Internet Web Site on Virtual Clinical Applications and Disease Management will expose students to a variety of resources on the Internet that can be used in solving virtual patient case studies. Resource links and case studies are being developed for this learning environment as World Wide Web pages. Students are provided with an on-line case then instructed to explore specific resources selected for that case as well as general resources which may or may not be related to the case. After building evidence and support for an accurate assessment of the problem state, students submit their assessment and treatment plan to the course instructor. Feedback is provided to the students once they have submitted their assessment in the form of a number of potential solutions to the case.

According to [Jacobson 1994], cognitive flexibility theory asserts that students who develop "flexible representations of knowledge" will be able to adapt that knowledge to a wider variety of problem settings (p. 146). Cognitive flexibility theory supports the use of hypermedia for learning and provides several design prescriptions for hypermedia that seek to promote flexible use of complex knowledge in students. Among these prescriptions are: using case studies to learn abstract concepts instead of learning facts that are removed from their context, presenting information from a variety of perspectives and representations, and stressing the complexity of knowledge over the isolation and decontextualization of knowledge [Jacobson & Spiro 1995]. When compared to traditional approaches that call for students to learn information apart from its context, materials designed according to cognitive flexibility theory (e.g., hyper-based cases) have been shown to promote transfer of complex knowledge to new settings [Jacobson & Spiro 1995]. Transfer means students are able to apply new knowledge to a variety of problem settings more readily.

[Jacobson & Spiro 1995] suggest students have different belief systems "related to the acquisition and structure of knowledge," and that these epistemic beliefs can "determine the type of cognitive resources the student accesses in performing learning and problem-solving tasks" (p. 305). The authors tested the hypothesis that students with complex epistemic beliefs who enjoyed active construction of knowledge via complex cases in multiple viewpoints and representations would be more successful with cognitive flexibility hypertexts. Students in an experimental condition receiving a cognitive flexibility hypertext treatment and who were tested to have complex epistemic knowledge averaged higher scores on a transfer-related, problem-solving essay task than students in the same treatment with less complex epistemic knowledge.

[Jacobson & Spiro 1995] point out "further research could collect data on the subjects' hypertext traversal patterns that could help clarify the relationship between epistemic beliefs, learning with hypertext, and knowledge transfer" (p. 327). When compared to their epistemic beliefs and scores on transfer measures, this information could determine whether cognitive flexibility theory is a valid approach for students with disparate epistemic beliefs. If students with simple epistemic beliefs are found to struggle with complex hypertext environments as seems to be the case, [Jacobson & Spiro 1995] suggest further research be conducted to "investigate how students with simple epistemic beliefs can be better prepared to use and learn from..." such instructional approaches (p. 327).

The use of social constructivist techniques (e.g., instructor scaffolding, cooperative learning) might be one way to enhance the performance of students with simple epistemic beliefs in complex learning environments. Combining elements of social constructivism with cognitive flexibility might prove beneficial for those learners unable to cope with complex processing. Where cognitive flexibility falls short of constructivism, according to [Jacobson 1994], is in the provision of social context and collaboration (p. 149). At least three approaches can be taken toward combining social structure with complex hypermedia environments. First, using assessments that measure epistemic beliefs [see Jacobson & Spiro 1995], students with varying beliefs about knowledge can be grouped with the assumption that more naive students would benefit from a pairing with students possessing complex epistemic beliefs. The impact of heterogeneous social grouping in a hypermedia environment was investigated by [Repman, Weller & Lan 1993] who discovered lower ability students may benefit from such a pairing, but with unclear effects on the higher ability students. Second, despite unclear effects of grouping by ability level, cooperative learning still seems to have merit in scaffolding complex environments. [Repman et al. 1993] suggest students working in groups go through a variety of processes such as "mutual guidance" and "disagreement over conclusions and tactics" (p. 286) which help them to restructure their knowledge. Third, the provision of scaffolding can help incorporate social structure into a complex hypermedia environment. A closed listserv used by students and instructors is one part of the pharmacy environment as a forum for questions and communication. The instructor, through responses and promptive listserv postings, will be able to scaffold student problem solving approaches to the case studies. Scaffolding requires that instructors know about strategies and techniques used in specific settings which can be applied to tasks and used to solve problems. Instructors, then, are able to cue and prompt students in the appropriate use of helpful methods and approaches as they struggle to learn confusing material.

Further research is warranted to study the effects of social support structure on students with complex epistemic beliefs who have already proven to be successful in such environments. How might the use of social supports undermine the development of complex knowledge structuring in students? If students rely on social structures too heavily, they may fail to develop the flexible knowledge that arises from active engagement, personal struggles, and trial and error. It seems evident that only those approaches scaffolding student struggles (e.g., strategy instruction) should be used in lieu of methods that lead students to answers not of their own creation.

IDEALS, A New Environment for Courseware Development, Course Delivery and Training

Professor Jouko Paaso, University of Oulu, director Raahe Laboratory of Computer Engineering, Finland, e-mail: jpaaso@tietoteku.ratol.fi

Dipl.-Inform. Max Mengel, ZGDV Darmstadt, Germany, e-mail: mengel@zgdv.de

Drs. Govert Gribling, Educational Technology Journalist, the Netherlands, e-mail: govert@worldaccess.nl

Abstract: The Ideals-project, which is sponsored by the European Union, aims at providing a system for flexible, on-demand, telematics based distance learning and training services to Institutes of Higher Education and Small and Medium Enterprises. A Modular Training System (MTS) that allows cost-effective co-authoring of courses and flexible learning for users, has been developed and a European-wide network of Local Training Centres (LTC) will be established. Learners log in, using the WWW, at the server located at their LTC and have access to the whole range of MTS-courses. The LTC also provides on- and off-line tutoring, possibilities for group-learning, records user progress and runs the administration.

Ideals' Modular Training System

The Modular Training System describes the hardware- and software-environment that is used for Computer Based Training (CBT) in the Ideals project. MTS supports in a multi standard technology platform: co-operative courseware production; course configuration; courseware database management; stand-alone learning; group learning; lecturing; administration of courses and course usage and individual user profiling.

Human interaction is assured through MTS' intrinsic communication services such as audio/video conferencing and course sharing mechanisms and in contrast to traditional CBT systems, MTS provides functionality not only for stand-alone but also for group scenarios. Re-use, i.e. upgrading of existing courseware, is easy in MTS and multiple use, i.e. the usage of courseware by many users, is supported. Naturally, all multimedia applications can be used in MTS. Ideals is an open client/server application (see figure 1) that has been designed to operate in nearly all computer and network environments and to grow with upcoming future demands.

Courseware

Authoring of courseware

The authoring environment is a critical issue in a CBT system. Course authoring is a complex process in which different expert groups need to cooperate. Therefore all participating groups have to be able to exchange annotations to enable teamwork within the production team. Since an intuitive graphical authoring environment is integrated into MTS, teachers and course creators without any programming skills can directly work with the system: layout and design information is integrated into units based on extended HTML so standard tools can be used to create self-contained courseware modules. These modules are checked into the courseware domain database along with a self-description to allow efficient search.

Three universities (Technische Hochschule Darmstadt, Germany; University of Oulu, Finland; University of Coimbra, Portugal) jointly create courseware on the topic *Fundamentals of Computer Graphics*. The universities are linked by satellite and ISDN. The costs and effectiveness of tools for cooperative authoring and on-line communication will be evaluated. In addition to its own courseware, each university uses material produced by the other two universities to build a customised course, resulting in a re-use factor of two (see table 1).

Fundamentals of Computer Graphics (FCG)			
Courseware Producers and Customisers	Equivalent hours of Courseware	Customised Course	Equivalent hours of Courses
TH Darmstadt	6.0	FCG1	16.0
University Oulu	9.5	FCG2	16.0
University Coimbra	8.0	FCG3	16.0
	23.5		**48.0**

Table 1: Cooperative Courseware Production

This pilot demonstrates individual and cooperative course production and configuration as well as individual and group learning, locally and remotely tutored, within a community of about 200 users.

A similar pilot, aimed at SMEs, concerning *Telematics Usage*, is also taking place.

Usage of Courseware

Learning can start right away from the WWW-browser. After login the trainee can start a new course, resume a saved course, issue a training-on-demand request or select a learning group. After working on presentation-, exploration- and examination units the course status is saved and the user profile updated. When requesting training-on-demand a search engine (see figure 1) selects the best fitting course node from the courseware domain and presents this to the trainee. Interactive learning can be added to any type of course usage at any time, either as expert consultation or by joining a learning group.

Benefits Offered by the Ideals-Methodology

Teaching fast developing new technology demands easy adaption of the learning material. In traditional systems changing the contents and/or the courseflow is in many cases impossible. In the Ideals system, tools for the authoring of learning material are integrated into the presentation software (a standard WWW-browser). These facilitate easy adaption of (parts of) the courseware.

Courseflow is user-adapted because the system records the student's progress automatically in a user profile which in turn effects the courseflow. Communication means facilitate group learning, tutoring and cooperative authoring.

Creating CBT material is very expensive. However, the re-use and multiple use of course modules in Ideals considerably decreases the cost of learning material per student while quality is assured by the different authors' specific expertise and the personalized courseflow and tutoring options.

For a more detailed description of Ideals MTS please refer to the Ideals homepage at: http://ideals.zgdv.de

Organizational and Methodological Development of a First-year Russian Course on the Utah Education Network

Alla Paroiatnikova, Assistant Professor of Business, Email: Paroiat@suu.edu
Bill O'Neill, Director of Telelearning, Email: Oneill@suu.edu
Southern Utah University, Cedar City, Utah

Abstract: This paper focuses on the organizational and methodological successes and pitfalls of a first-year Russian course taught over the Utah Education Network in 1996/97. Both on-campus students and distant students from five rural high schools were enrolled simultaneously. Organizational issues included student and faculty training, incentives for faculty, increasing the number of microphones available and the use of fax instead of email. Methodological concerns were difficulties of adjustment to the learning environment, the size of the class, feedback strategies and methods of dealing with student anxiety.

The Utah Education Network provides a two-way interactive television system linking the state colleges and universities and state high schools and regional education centers. A priority of the state is to provide college-credit general education courses to qualified high students---concurrent enrollment. During the 1996/97 school year Southern Utah University (SUU) provided a full year of introductory Russian language courses to students in five rural high schools in southern Utah. For several years SUU conducted general education courses over the Utah EDNET system as well as upper division and graduate level courses but this was the first experience in teaching a foreign language.

Several new technical and organizational issues arose while others that were lingering became even more apparent. SUU was able to deal successfully with some of these concerns while others are yet to be solved. Faculty incentives were a significant issue. Faculty teaching concurrent enrollment are now able to count the course as an 'overload' as well as 'on contract'. Also, we found that language courses require nearly one microphone per student which we were able to provide. It is helpful if distant students in rural high schools are comfortable with the technology before instruction begins. The week before university instruction commences, SUU will conduct a training session for distant students to assist them with obtaining email accounts, information on student support issues, library access, study skills for success in college as well as in a technologically enhanced learning environment.

However, because it is a state-wide system, the receive-site facilitators are not responsible directly to the university and are not always satisfactory. High school bell schedules do not coincide with each other and do not match the timing of our courses.

METHODOLOGY

This language class had a strong emphasis on oral language skills and a communicative approach implies interaction which is naturally more difficult in telelearning environment. Thus, in the course of instruction on EdNet, the major goal was conquering the distance both technically and psychologically. In this regard, works by Barbara McKenzi and colleagues (Mckenzi et al, 1996) and Morris L. Beers (Beers and Orsech, 1996) provided invaluable guidance and insight and helped to avoid or minimize some pitfalls in preparing the course. However, other "gremlins" showed up in the process of course delivery, to name just two most disturbing: adjustment to the new learning environment and increased level of debilitating anxiety.

1. A class comprised of on-campus students (30) and high school students at five sites (28) required adaptation of the course and integration of new media and new teaching strategies to meet student needs. Adjusting to this new technologically-enhanced environment proved to be difficult and often frustrating to both groups as was

reflected in end-of-term evaluations. Additional efforts had to be made to cope with this situation which resulted in slowing down the instruction process. Overall about 15 to 25 percent of time in those type of classes should be planned beforehand for dealing with specific technical and psychological problems, especially in the first course of the series.

In the second quarter the instruction process went much smoother since the students felt more comfortable and relaxed.. They were also used to the structure, procedure and requirements of class which was demonstrated by improved academic performance. The size of the class was another important factor. In the second quarter 31 students enrolled in the course (12 on campus and 19 at 4 sites) which proved to be a more manageable size both technically and psychologically.

Short turn-around times (from students sending assignments to the university until the time the assignment with the instructors' comments and corrections) are of particular importance in effective language acquisition due to the increased danger of perpetuating mistakes. Teaching Russian on EDNET in regard to this aspect was made difficult because of the alphabet differences. Obviously, we couldn't use email which would have required the purchase of special software and training students to use a different alphabet keyboard. The difficulty was solved by using fax to transmit assignments which was a costly operation but necessary for quick feedback.

2. Psychological aspects of this telelearning class were considered of primary importance for its success taking into account communication as the goal of instruction and interaction as a mode of language acquisition. The major issue to be addressed was finding effective ways to deal with debilitating levels of anxiety which are particularly high in the situation of increased interpersonal distance and exposure to several different audiences. The "one classroom" approach was chosen to deal with this issue. Camaraderie is a very important factor in learning a foreign language since "familiarity, trust, and comfort with others act to boost students' certainty that their actions will be well received and their attempts at communication will be welcomed, or at least not ridiculed or scorned." (Pellegrino, 1996 p.7)

Teamwork was chosen as the main mode of classroom activity, which included teamwork at sites and cooperation and interaction between sites. As far as teamwork at sites is concerned, it was successfully developed during the first 3 to 4 weeks. Interaction was developed in the second quarter when students felt more relaxed and willing to interact with other sites. This factor can also be attributed to improved language skills.

An important component in the efforts to minimize the anxiety was the testing technique. Since it is the outcome that is important in foreign language acquisition, the intermediate tests were not graded and students did not gain or lose any points for their final grade as a result of these tests. The test was called "control work" and was undertaken to check language progress. The tests were analyzed in class and the distant students faxed them to the instructor for the second review. That process helped to decrease anxiety and fear of failure and to establish a healthy attitude toward tests, correction of mistakes and progress in language studies.

The year-long course has not be completed at the time of this writing. The final results await analysis at year's end.

Exploring Personal Identity and Social Justice in 3-D Cyberspace

Jonah H. Peretti
Academic Computing
Isidore Newman School, USA
jperetti@newman.k12.la.us
jonah@well.com

Abstract: Internet based virtual reality is allowing students to explore personal identity and social justice on the World Wide Web. Virtual worlds provide unprecedented methods for teaching perspective-taking and critical thinking. Role-playing in simulated environments will become increasingly accessible to educators. The Virtual Reality Modeling Language (VRML) offers exciting new ways to encourage students to actively participate in learning. This paper presents the first steps in Isidore Newman's ongoing work to integrate three-dimensional media across the curriculum.

Multi-user, real-time, interactivity in three-dimensional virtual worlds is now available on the Internet. Access to these worlds is becoming available to a broad range of educators and has the potential to radically change pedagogy. Drawing on lessons I taught 10th grade students at the Isidore Newman School in New Orleans, this paper highlights emerging possibilities created by Internet-based, non-immersive Virtual Reality. In particular, I focus on the opportunities for exploring personal identity and social justice. Yesterday's science fiction is beginning to find a place in today's classrooms. It is imperative that the next generation of teachers and students be acquainted with the three dimensional frontiers of cyberspace.

Participants in virtual worlds invent complex and nuanced fictional identities and interact with other people without revealing their real life identities. Working in pairs, the students created a sociological profile for their character that included the social categories they felt to be most important. This exercise provoked discussion about race, class, gender, geography, sexual orientation, and age. Students struggled to imagine themselves living a life and inhabiting a body very different than their own. Once their character was developed, a new "person" was ready to be born into cyberspace.

Using a shareware Virtual Reality Modeling Language (VRML) browser, my students were able to enter 3-D, multi-user worlds and interact with other people. First, they picked out a 3-D virtual body, called an avatar, that became the visual representation of their character. Then, they created a "public card" that contained information about their character that everyone in the virtual world can access. The body and card express the identity that was elaborated in the sociological profiles. Once a character has a body and a public card, s/he is ready to venture out into social space to interact with others. The students searched the virtual world for interlocutors and engaged in lengthy real-time conversations with people from around the world. Students used these interactions to develop, explore, and further elaborate their virtual identity.

The software we used allowed my students to save transcripts of all their conversations which provided a resource for evaluating the conversations they had. Each student wrote a report about their experiences in cyberspace. They addressed the following issues: Who wanted to talk to you? Who refused to talk with you? Which social categories were most important to you and your interlocutors? When and how did issues such as race, gender, or class come up in conversations? What prejudices did people exhibit? They also addressed issues that related specifically to constructing virtual identities. Would this study be different if you were interviewing people face-to-face? What difficulties and joys did you experience creating a virtual identity? What is the relationship between your real life identity and your virtual identity?

The lesson provided my students with hands-on experience creating social and personal identities. Sociology and psychology are very theoretical disciplines. VRML environments allow students to put abstract disciplines into concrete practice. The practice of inviting students to participate directly in educational worlds can be used effectively across the curriculum. I can image history classes role-playing revolutions, English classes performing collaborative, globally accessible plays, biology classes navigating 3-D simulations of cells, organisms, or ecosystems, and foreign language classes traveling to distant lands and speaking in foreign tongues. Indeed, we may soon participate in academic conferences that take place entirely within 3-D cyberspace.

Young Americans on America: Bridging Cultural and Geographic Diversity

Abstract: This paper describes a telecommunications project that brought together a network community made up of students from six culturally and geographically diverse American high schools, humanities scholars, and representatives from the Virgin Islands Institute for Teaching and Learning. During a series of video conferences and Internet discussions, participants met to explore the variety of race, ethnicity, and culture that enriches our country and the values that we share as Americans.

Introduction

Young Americans on America: Bridging Cultural and Geographic Diversity, is a telecommunications project which utilized interactive video conferences and Internet technologies to conduct a national conversation among six public high schools across America and the territory of the United States Virgin Islands. Students participated in five one-hour video conferences over a period of five months. Students also had access to a web site that provided discussion forums, chat rooms, and resources on race and ethnicity.

Goals of the Project

The project allowed experimentation with new ways of using technology to further multicultural communication and awareness. The project made it possible for students of various racial, socioeconomic, and cultural backgrounds to interact with others whom they would not have met. Therefore, this project reinforces the purposes of the National Conversation, as stated by Sheldon Hackney, Chairman of the NEH:

> [We]...have a responsibility to examine and discuss what unites us as a country, what we share as common American values in a nation comprised of so many divergent groups and beliefs. For too long, we have let what divides us capture the headlines and sound bites, polarizing us rather than bringing us together [Hackney 1996].

Project Participants

The following six schools participated in the conversation: Charlotte Amalie, Virgin Islands; Fairfax, VA; Boston, MA; Chicago, IL; Austin, TX; San Francisco, CA. The schools were varied in access to technology and socioeconomic status.

Video Conferencing and Conversation Facilitation

The project consisted of six conversations which occurred once a month. Prior to each conversation students were assigned readings and assignments concerning race and ethnic relations. These readings matched the theme for the conversation of the month. In order to facilitate dialogue, one-hour video conferences were used to lead off each monthly conversation. This enabled students to see each other and to converse in real time. A moderator controlled the flow of conversation between the video conferencing sites in order to ensure that each school had equal opportunity for participation. Each one-hour video session began with a ten minute statement from a humanity scholar concerning race and ethnic relations in America. Next, each school was given the opportunity to comment on the scholar's statement followed by open discussion.

In order for students to gain an understanding of the diverse nature of the schools involved in the project, each school took turns in presenting information on their culture and way of life. This along with the reading assignments were designed to facilitate group conversations as well as individual participation. Students indicated enthusiasm about the utility of the video conference conversations. The video conference allowed a unique opportunity to engage in face-to-face dialogue with students from diverse ethnic and racial backgrounds. Students became aware of the value of diversity and its role in American society.

Interactive Web Site and Conversation Facilitation

In order to facilitate ongoing group and individual participation a World Wide Web site was developed for the project. Since each video conference lasted an hour, students were often left with a desire to continue threads of discussion. The web site provided discussion pages to which students could post comments. Students were able to post comments and view previous comments from other participants. This design was effective since students did not have email accounts. A chat room was also available along with a polling section that allowed participants to cast votes on various topics. The web site also provided profiles on each student which consisted of a photograph and a written statement about themselves.

These types of web-based activities enhanced the conversation by allowing students to dialogue during the course of the month. Though some schools were hampered by limited access to the Internet, student participation in the web site was high. The web site provided a much needed support for the video conferences by creating a place for students to meet and discuss issues. Students also liked the ability to find student profiles to gain more information about the other participants.

Acknowledgments

The project was conducted by the Virgin Islands Institute for Teaching and Learning with funding being provided by the National Endowment for the Humanities' initiative entitled A National Conversation on American Pluralism and Identity. AT&T funded the video conferencing and the web site was hosted by the Institute for Technology and Learning (ITAL) at the University of Texas at Austin.

Special appreciation must be extended to the five Humanities scholars who actively participated in the conversation: Dr. Asa Hilliard, Dr. James Anderson, Dr. Marilyn Krigger, Dr. Waldemar Rojas, and Dr. Richard Spillane. The series was moderated by Dr. Eric Cooper, Executive Director of the National Urban Alliance at Columbia University.

The project director was Dr. Linda Creque, Executive Director of the Virgin Islands Institute for Teaching and Learning. Patricia Platt was assistant Director in charge of technology.

The Role of Visual Testing When Learning from Instructional Multimedia

Abstract: A field experiment was conducted to test the hypothesis that after completing an Interactive Multimedia (IMM) program, students who receive visual testing will obtain higher achievement scores on identification, terminology and comprehension tests compared with verbal testing. Sixty two post secondary Emergency Medical Services students were randomly assigned to one of two groups. Both groups completed the same IMM lesson and two sets of evaluations. One evaluation was given immediately after the IMM lesson; one group was evaluated by visual testing and the other group by verbal testing only. The second evaluation was given later and the testing modes were reversed for the groups. Data were analyzed using repeated measures analysis of variance and Scheffe´ pairwise comparisons. A significant difference favoring visual identification tests was found. Several plausible hypotheses to account for the findings and recommendations for application and further research are presented.

Introduction

Research into visual testing using paper and pencil techniques has shown that students who receive instruction and evaluation complemented with visual displays achieve higher levels of performance when compared to those who don't receive evaluation complemented with visuals [e.g., Dwyer 1985; Dwyer and De Melo 1983; Dwyer and De Melo 1984; and Szabo et al., 1981]. Are these research findings transferable to learning and evaluation in an IMM, i.e., computer environment? Some research into the role of testing within microcomputer based instruction (MCBI) [Mayton, 1991] suggests that visual testing is just as effective or in some cases more effective in evaluating learning by MCBI.

Visual Testing Theory

Batting [1979] reiterated the concern that any difference between the retrieval environment and the original learning environment produces marked decrements in the learner's performance. Morris, et al. [1977] transfer appropriate principle implies that information processing must be appropriate to the intended use of the information. Tulving and Thompson's [1973] encoding specificity principle assumes that recognition memory is better if the cues used in the original instructional/acquisition environment are used in the testing/retrieval environment. Research by Batting [1979] has shown support for the encoding specificity principle. Paivio's [1986] dual coding theory recognizes both verbal and non-verbal processing and postulates verbal and visual cognitive subsystems for encoding and retrieval of information.

A Field Experiment

A field experiment was conducted to test the hypothesis that after completing an IMM program, students who receive visual testing will obtain higher achievement scores on identification, terminology and comprehension tests compared with verbal testing. This experimental study investigated the effects of two levels of the independent variable, (verbal or verbal plus visual testing) on the three dependent variables, (scores on identification, terminology and comprehension tests). Sixty two post secondary students in an Emergency Medical Services certification program participated in the study on a mandatory basis. Subjects were randomly assigned to one of two research groups. Both research groups completed the same IMM lesson and were then given to two sets of evaluations. One evaluation was given immediately after completing the IMM lesson; one group was evaluated by visual testing and the other group was evaluated by verbal testing only. The second evaluation was given within one to seven days later and the testing modes were reversed for the groups.

The content allowed the evaluation of learning objectives that involved identification, terminology and comprehension and was delivered by a program-directed, self-paced IMM lesson using a multimedia-capable computer which took an average time of one hour. The visual displays presented information that was identical to the text information. Color, audio and dynamic visual displays were used to differentiate various components of a graphic illustration.. Students completed rehearsal activities with corrective feedback. One achievement test measuring identification, terminology and comprehension with visuals used during instruction was developed from the lesson's learning objectives. The verbal version contained only text in the questions and answer choices. The visual version had text information complemented with visuals within the question or the answer choices.

Results

T was no significant difference between standardized means of the verbal and verbal plus visual test groups. There was a significant effect ($\underline{F}$ (1,60) = 32.8, $\underline{p}^{2}0.05$) reflecting that the visual testing mode had a higher mean score than the verbal testing mode for the identification test. A post-hoc Scheffe′ test showed Group 1 and Group 2 visual test scores were higher than Groups 2's verbal test scores. Results indicated no significant difference between groups, testing mode or between groups and testing on immediate or delayed terminology tests. The ANOVRM test results indicated no significant difference between groups, testing mode or between groups and testing.

Discussion

The results of this study lend partial support for part of the study's hypothesis, i.e., students who receive visual and verbal testing obtain higher achievement scores on identification tests when compared with those who received verbal testing.

Several hypotheses to account for the findings have been suggested. They include the type of rehearsal activities used in the IMM lesson, the students' lack of familiarity with visual testing, the relationship between text and visuals, the types of visuals used for visual testing, the high competency requirements of the IMM lesson content and the novelty of learning by IMM. Suggestions for further research were presented.

Abstract: This paper addresses the experiences of two multimedia professionals who often use email to communicate with students and commercial clients. Email has become a convenient and powerful means of "conversing" and providing feedback. It examines three key areas: (1) the addictive quality of email, (2) student communication with email, and, (3) optimizing email use.

Electronic mail (email) is often underutilized in the teaching/learning process. This software application is underestimated in terms of its capability. We content that the greatest advantage of email in instructional settings is its use as a feedback medium. The ability to provide immediate and personalised feedback makes email an addictive communication tool.

Email is often the first "networked" application or communication software individuals learn. Many universities assign an email address to each student during their orientation. Once on-line, students find the power connected with the ability to quickly and inexpensively communicate with another individual or multiple individuals addicting.

Initially, the power of email must be demonstrated to the individual. A good means to gain an individual's acceptance is to establish a connection to a list-serve on a topic of interest. Another method is to encourage an individual to find their friend's and families' email addresses. The feedback capabilities of email must also be demonstrated to the individual. Feedback using email is similar to the traditional face to face situation with students and clients. Immediate feedback on performance results is essential for learning to occur.

The use of email with students reinforces the power of email. Although in their study on student attitudes toward electronic mail, Wissick et al (1995) found that students even without high faculty involvement had positive attitudes towards electronic mail, they found students who received more faculty messages were more positive towards electronic mail. The number of email exchanges can be increased by requiring students to converse with the instructor and submit assignments to the instructor via email. Even when the excuse, the network was down, is used the student can always re-send the message. Most email packages save a copy of any sent mail.

To further increase email exchanges, students can be matched with one or more of their classmates to develop a final project in a course. A requirement of at least one email message a week can further stimulate email interactions. . D'Sousa (1991) found that email led to greater communication among class members as well as between the instructor and students. In an Informatics course offered at the UT School of Public Health some "project partners" exchanged as many as ten email messages during week describing their views and ideas on the final project.

During the 15 weeks this course was offered the faculty member and students generated over 1400 messages. The faculty member exchanged at least one mail message, more often two, to each student every week creating a total of 677 messages sent during the 15 weeks. The student responses and interactions generated another 789 messages.

Given this volume of email, the students began to comment on the communication aspects of email beyond the assignment requirements. As they became more accustomed to communicating by email, they needed to be informed of how to use the medium effectively. They began to comment on some common traits running through the messages. They began to notice that some email messages are easier to read and understand than others.

Coaching in the use of the email was given and included: writing a good subject line, line length brevity, terse prose, message length, displaying emotion and common jargon. Specifically, students were given the connections between email and theories of communication and learning. The first component is gaining the viewer's attention. The use of the subject line is considered the "headline" of the email message. A headline's function is to quickly grab the viewer's attention and inform the receiver of the nature of the message.

In composing the message students were made aware of a common email problem - message line configuration differences. One package may allow for an eighty character line length and another may be limited to forty characters. If an eighty character email package is used to send a message to an individual with a forty character email package, the adjustment to the forty character limit can make the message difficult to read.

Brevity is the beauty of email. Students quickly found that very long email messages are difficult to read. To help emphasize the need to keep the message brief, students were introduced to common jargon used in email communications. Common jargon such as ASAP and FYI are easy to comprehend. However, BTW and IMHO are not. These two abbreviations are very common in email. BTW(By The Way), IMHO stands for In My Humble/Honest Opinion).

Again, the ease, the near instantaneous communication, and the lack of "need to purchase" postage stamps encouraged the students to send more messages. As they begin to send more and more messages, the messages tended to become shorter and more succinct. Interestingly, the composition of the messages in the Informatics course while terse and business-like on the project discussion, would overall become very conversational as the weeks passed. Students often composed their email messages the way they would speak to classmates in person. Although they had been encouraged to use the KISS principle in sending email, they began to weave in information on their families, studies and other personal items.

Because of this "personalisation," the need to inject some emotion into the messages lead to an examination of ad hoc email standards. Students were informed that messages in ALL CAPS IS CONSIDERED AS SHOUTING. Smiley faces :-) , frownies :-(, and winkies ;-) are often the first of the emoticons introduced. However there are many, many variation of these they can learn to attach an emotion to a particular paragraph, sentence or word.

Encouraging students to use email as a form of communication is the first step in the "addicting" them to instructional computing. The next step is to build their confidence by assigning specific tasks to be accomplish via email. Finally, providing students with the skills to use email effectively increases the likelihood they will continue to use email in their everyday affairs.

New Directions for Dealing with Copyright: Archive.edu

Bernard Robin, Department of Curriculum and Instruction,College of Education, University of Houston,USA
brobin@uh.edu

Sara McNeil, Department of Curriculum and Instruction,College of Education, University of Houston,USA
smcneil@uh.edu

Abstract: Educators at the University of Houston have developed Archive.edu, a Web site that serves as a storehouse of technology-related instructional materials that can freely be downloaded and used without copyright restriction. In addition to being an online resource center, Archive.edu also serves as a gallery for educators and their students to share their projects with the Internet community.

A longer version of this article with illustrations is available on the CD-ROM.

As the World Wide Web continues to evolve, there are a number of issues that are of concern to educators. One important issue is that many schools, districts and classrooms are now developing their own Web sites to showcase the work of students and faculty. This is becoming easier and more common as just about all educational institutions are being connected to the Internet. The creation of Web sites is also being facilitated by the rise in the number of new, inexpensive and user-friendly Web editing programs available on a large scale. The number of commercial Web sites is also increasingly rapidly and this ever-growing abundance of information can be overwhelming for many Web users. The volume of material makes it difficult and often frustrating for users to easily locate useful information. Even with the development of newer and better search engines, many educators do not possess the skill needed to find the information they need. Perhaps most significantly, much of the material that is available on the Web has not been designed for instructional purposes and there still is a lack of ready-to-use resources for the average student and teacher. When educators do find information they wish to use, they must re-design and repurpose this material.

A significant problem for educators is that many, if not most, of the material on the Web is copyrighted and may not be incorporated into instructional projects. For example, the Discovery Channel Web site (http://www.discovery.com/) contains a wealth of valuable resources in the form of text, graphics, audio and video clips. This material may be viewed without restriction, but cannot be modified or reproduced in materials created by students and teachers for later distribution online. The irony of this situation is that the ability to download material is becoming faster and easier as the Web evolves into a more user-friendly resource. To download a graphic, for example, the user only needs to click and hold on the image and a dialog box appears that allows the user to save that image on their own computer. In addition, the Web is rapidly becoming a multimedia-capable environment where audio and video materials can be heard and viewed within the browser itself. This ability allows users to easily save these resources to their own computers, and especially in education, to incorporate these resources into their own multimedia projects.

The Confusion Over Copyright Laws

There has been much discussion recently about what is legal and ethical regarding copying and using works created by others, especially the use of electronic material found on the Internet. The ease with which information may be copied from the Web has forced many developers and users to consider the issue of intellectual property. Copyright laws for the electronic dissemination of information are still evolving, and most educators are unclear about their rights and responsibilities.

Copyright law, simply stated, means that legally one is not allowed to take someone else's words, graphics, video, or any other type of media and use it for their own purposes. However, the long-standing tradition of "educational fair use" allowed many educators to feel comfortable using parts of other people's works for instructional purposes as long as those materials remained within the walls of the classroom. But education today does not always remain within an isolated classroom. Many schools are developing their own Web sites and sharing the work of their students and teachers with the world. A potential copyright infringement problem occurs when, for example, students surf the Web, download graphics or audio clips, insert them into their own work, and redistribute this "borrowed" material on their school or classroom Web site. This situation has forced educators and legal experts to reconsider the issue of what is legal in the world of digital manipulation and electronic publishing.

There are numerous Web sites that deal with copyright and its implications for education. One of the best resources for copyright guidelines and information may be found at the University of Texas Crash Course in Copyright Web site located at http://www.utsystem.edu/ogc/intellectualproperty/cprtindx.htm

What is Needed

With the proliferation of computers within classrooms, connectivity to the Internet, and the desire to produce educational Web pages, teachers and students are searching for ways to utilize technology instructionally. However, a growing body of research indicates that many educators would like to develop multimedia materials that can be used in their classroom but do not possess the knowledge and skills necessary to do so [U.S. Congress, OTA 1995]. The authors have found that many educators are helped by being able to see specific examples of how technology can be used to support the curriculum. Because of the dramatic growth of the Web, many educators are now beginning to think about how technology can be used to motivate students and are seeking models for developing online instructional materials that can be disseminated over the Web.

The authors have been working on the development of a teaching model for developing meaningful instructional projects online. This model has four major components:

- a plan for developing copyright-free resources
- an example of a multimedia project, stack, or presentation
- a description of how this specific example of multimedia is used in the classroom
- step-by-step instructions for creating similar multimedia materials

In most educational Web sites, one or more of these components may be found. For example, there are numerous good examples of multimedia projects on the Web. There are also many theoretical models of how multimedia can be used in education. In addition, there are many Web sites that focus on how to use certain software applications to create multimedia projects. However, there are relatively few places where all of the components, the project itself, how the project can be used instructionally, and directions for creating new copyright-free projects, are found together so that the entire development process is documented and may be studied, not in isolation, but as a complete, integrated unit.

Archive.edu

To continue the development and dissemination of this model and to make instructional resources that educators can use in their classrooms more accessible and downloadable, the authors have created Archive.edu. This Web site will serve as a storehouse of instructional materials on a variety of topics that educators can easily access and have permission to download any of the materials. These materials can be used as they are, or customized and incorporated into other instructional projects. Materials in the archive will supported by other components of the model. For example, not only can a user download an animated GIF file that demonstrates a mathematical concept, but they will also find step-by-step directions for creating animated GIFs, as well as links to related Web resources. The design and development of Archive.edu's interface and information hierarchy has evolved through interviews with educators and students who have expressed an interest in locating educational materials on the Web and plan to use this resource. The prospective audience for Archive.edu includes preservice and inservice K-12 teachers and technology coordinators, university faculty and students, and others interested in educational materials.

Copyright issues continue to be a primary concern for educators who want to use, create and disseminate instructional materials via the Web. Archive.edu is an attempt to solve some of the problems associated with copyright by providing a place where educators can share resources without worrying about violating someone else's intellectual property rights. For Archive.edu to become a truly worthwhile resource, it is necessary that educators can submit copyright-free resources that they and their students create and are willing to share with others in the educational community. The authors and their students have begun the process of "seeding" Archive.edu with useful instructional materials. It is our hope that the Web site will be an entry point for students, teachers and faculty to actively and creatively use technology to develop and share their own copyright-free resources and to take advantage of the collaborative mechanisms that the Web provides. The URL for Archive.edu is: http://www.coe.uh.edu/archive

Shakespeare's Language: An Interactive Computer Program for Students of Shakespeare's Plays

Randal Robinson
Department of English, Michigan State University, U. S. A.
robins29@pilot.msu.edu

Abstract: Most students come to Shakespeare's language prepared to look for obsolete words but not other, more important causes of difficulty: familiar words with unfamiliar meanings, words that contain familiar suffixes with unfamiliar meanings, constructions from which speakers omit words, constructions in which speakers arrange words in unusual ways, words and phrases with syllables or parts of syllables missing, and words with unexpected implications and connotations. *Shakespeare's Language*, developed on SuperCard by Randal Robinson and Peter Holben Wehr, prepares students to recognize and respond to these additional causes of difficulty.

As I learned in doing research for the booklet *Unlocking Shakespeare's Language: Help for the Teacher and Student* (published by the National Council of Teachers of English in 1988), most students come to Shakespeare's language ill-prepared to find the most important causes of difficulty in that language. They know to watch for obsolete words, but not other, more important impediments. These other causes of difficulty we can place under six headings: 1) familiar words with unfamiliar meanings (examples are "abuse" meaning "deceive" and "let" meaning "hinder"); 2) words that contain familiar suffixes with unfamiliar meanings (examples are "awful," meaning "awe-inspiring," and "comfortable," meaning "comforting"); 3) constructions in which speakers arrange words in unusual ways (Othello, for example, arranges words in an unusual way when he says, "That handkerchief / Did an Egyptian to my mother give"); 4) words and phrases with syllables or parts of syllables missing (examples are "'Sblood" and "ta'en"); 5) constructions from which speakers omit words (Perdita, for example, omits words when she says to Florizel, "Now Jove afford you cause" and means, "Now Jove afford you cause for blessing the time"); and 6) words with unexpected implications and connotations (for example, pronouns such as "thyself" and the "me" in "me cranking"; verbs such as "come" and "afford" when they have "let" and "may" implied; and uses of metaphor and personification such as we find in Juliet's "Come, civil night ... , / And learn me how to lose a winning match, / Played for a pair of stainless maidenhoods").

Because most students have not learned to watch for such elements, they usually fail to identify those elements and so fail to work out the true and full meanings of those elements and the passages in which they occur. Consequently, the students become confused but do not know why they are confused, and then, seeking rational explanations for their failures, they conclude that they must be deficient human beings who are simply too stupid ever to read Shakespeare well. They turn against themselves, against the teachers who have led them into failure, and against the language of William Shakespeare.

Peter Holben Wehr and I have developed a SuperCard program (for use on Macintosh computers) to help students adjust to Shakespeare's language. The program, called simply *Shakespeare's Language*, has at its base a scheme of nine classifications. These classifications, which the program introduces through demonstration units and menu items, resemble the *topica* of classical rhetoric. They give students concepts and categories to use in searching, and they help students develop new and necessary mental *schemata* as readers. The short titles for these nine classifications are Familiar Word, Obsolete Word, Suffix, Pronoun, Verb or Verbal, Omission of Syllable, Metaphor or Personification, Arrangement, and Omission of Word.

These nine classifications all hold promises of celebration and assistance. The student who uses them well receives bursts of music, complimentary messages, interlinear translations, explanatory notes, covering fields with words rearranged for lucidity, and similar fields with implied words made explicit. To obtain the rewards that the program keeps in store, the student must first open a cutting from one of Shakespeare's plays (the program provides cuttings from nine plays, and each cutting covers 54 to 160 lines). Then, having read the Shakespearean text, which appears in a scrolling field to the right of the screen, and having read also an introduction to the text made available through a menu, the student must select and classify words and segments with which he or she wants assistance.

The student may select the word "portly," for example, by clicking on it and may then classify that word by using the Familiar Word button on the Palette, which sits at the left of the screen. If the student performs these two actions in sequence, the program will respond with a bit of music and a congratulatory message taken from a speech of one of Shakespeare's characters (for Familiar Word the message is, "A very good piece of work, I assure you"). Then the program will put under the word "portly" the translation "well-behaved," using a color that matches the color of the Familiar Word button on the Palette.

Or the student may select a word that requires a note, not a translation. For example, the student may choose such a pronoun as "thy," such a verb as "afford," such a personification as "night," such a contraction as "ta'en," or such a suffix-bearing word as "awful." After the student chooses and correctly classifies such a word, the program provides not only music and a complimentary message but also an explanatory note in a scrolling information field.

Also, a student may select from the Shakespearean text not a single word but a segment of one-half line to four lines (the program provides the student assistance in locating troublesome segments by listing in its menus the numbers of the lines in which such segments appear). After selecting a troublesome segment, the student may classify it by using the Arrangement button or the Omission of Word button on the Palette. For example, after reading "Were the world mine, Demetrius being bated, / The rest I'ld give to be to you translated," the student might select the second line, classify it by using Arrangement, and then receive a temporary covering field that makes the text read: "Were the world mine, Demetrius being bated, *I'ld give the rest to be translated to you.*" Or, after reading Juliet's "Saints do not move, though grant for prayers' sake," the student might select the second half of the line, classify the selection with Omission of Word, and then receive a temporary covering field that presents this amplification: "Saints do not move, though *they do* grant for prayer's sake."

In using the program in this manner, the student learns a classification system for the difficulties in Shakespeare's language and, by learning that system, learns to fix on elements that most need attention. Furthermore, the student learns to recognize and avoid mistakes in classification that are common among developing readers (the program responds to each mistake by offering short harp-like sounds and a recommendation that the user try another classification). For example, the student learns to avoid treating a familiar word with unexpected meaning as if it were a metaphor, learns to avoid treating an elliptical segment as if it were a segment with words strangely arranged, and learns to avoid treating such a word as "thee" as a word that needs a mere translation.

Then, too, in using this program, the student learns various modes of response for various difficulties. By its translations, explanatory notes, rearrangements, and amplifications, the program models responses that all expert readers practice habitually, sometimes unconsciously. The program also models another kind of response that I have not yet mentioned. Sometimes, after a student clicks on an icon that has appeared above a familiar pronoun, metaphor, or personification, the program puts a series of icons over words related to that pronoun, metaphor, or personification. Thus, the program associates words in a character's speeches or the speeches of two or more characters.

In brief, then, *Shakespeare's Language* helps students discover the pleasures that Shakespeare's plays afford by helping them adjust to the language of those plays. It provides ample opportunities for students to practice significant reading activities, as a mere booklet cannot, and it helps students develop confidence in their own abilities. It also removes the teacher as intermediary and permits the students to become what all students must ultimately become: teachers to themselves.

An Interactive Environment for Digital Electronics Learning and Design

M.J. Moure-Rodríguez
M.L. Rodríguez-Pardo
M.D. Valdés-Peña
E. Mandado-Pérez

mjmoure@uvigo.es
Departamento de Tecnología Electrónica
Universidad de Vigo
SPAIN

Abstract: The main objective of Electronic Engineering learning, is the development of the student's capacity for implementing real systems. This supposes the ability to design, simulate and test electronic circuits. Traditional Electronic Instrumentation and professional CAD tools are very flexible and feature a lot of options. Nevertheless, its use in the first course of Electronic Engineering is not adequate because students will never exploit all their possibilities. On the other hand, much time devoted to understanding very complex manuals is required by the students for mastering these tools, slowing down the learning of fundamental design concepts.

By contrast, the use of educational oriented CAD tools, is a suitable solution. They improve the teaching-learning process, offering the same basic options of professional ones and avoiding their drawbacks. In this way, an integrated software package [VISCP (Virtual Instruments & Schematic Capture Programs)] intended to guide students through all stages of electronic systems prototyping, is proposed [Moure 96].

Schematic Capture Program (SCP) of VISCP. Advantages and functionality.

The SCP has a simple interface that allows students to master the program performance in a short space of time. The program operates over Windows environment, where all programs present a similar graphic user interface that makes them easy to use [Alessi and Trollip 1991].

In addition, the SCP is oriented to educational applications. It has been designed to help students in the design task by: 1) preventing typical mistakes in designs carried out by students; 2) avoiding graphical design errors by clearly showing the electrical connections between the system components; 3) allowing students to link their designs with commercial programs.

As opposed to traditional programs, the fundamental components of SCP are standard integrated circuits instead of logic gates [Fig. 1]. This characteristic ensures a direct relationship between the schematic and the real design that the student is going to assemble, making the understanding and test of the circuits operation easier [Mandado 96].

The Virtual Instrumentation Module of VISCP.

The virtual instrumentation technique is based on combining a computer with a simple and general data acquisition system in order to define a specific measuring instrument. In other words, the hardware of the system consists on the proper hardware of the computer plus a general purpose data acquisition system. Meanwhile, the functionality of the instrument is provided by the software. The main advantages of this approach are the following:

- The hardware is common to any instrument so the use of resources is more efficient. Using the same hardware, software modules can be developed in order to generate different instruments like an oscilloscope, a logic analyzer or a multimeter.

- Operation mode is determined by the software. In this way, the control panel can be adapted to the application, according to the requirements of the student level.
- Virtual Instruments use the resources of the computer like, for example, the graphic monitor to represent their results. Using actual multitasking operating systems two screens of different active programs can be represented simultaneously.

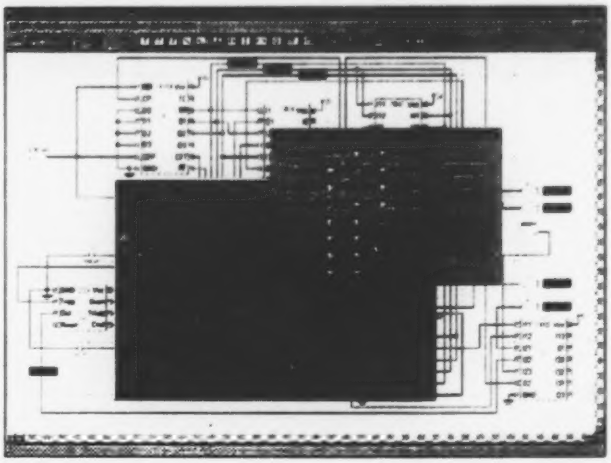

Figure 1: Screen of VISCP.

The virtual instruments can take advantage of real windowed operating systems and the similar interface of its applications. Therefore, if the students need to save some data recorded by the virtual instrument they know that they can find this function on the File Menu of the program. Instead of this, the way of accomplishing the above task in a traditional instrument depends on the manufacturer and the kind of instrument.

Virtual Instruments developed in VISCP are designed to be programmed graphically. For example, logical options are selected using "check-box" controls [Fig. 1]. Also, like in the schematic capture application each control provides a on-line help describing its function.

Multiple instruments of the same or different kind can be created by the student at the same time. The number of signals that can be displayed simultaneously is limited only by the data acquisition system. The same signal can be displayed using different instruments assisting students in the choice of the best instrument for the visualization of a specific signal according to its nature.

Up to now, two virtual instruments for Digital System verification have been developed: a logic probe and a logic analyzer [Fig. 1]. Nevertheless, new instruments can be created by only programming their specific characteristics. The Digital Circuits test is completed with a test vector generator that permits the verification without any external stimulus. In this way, the PC is the unique equipment required for the prototype test.

Due to its educational orientation the Validation tools for the system operation are included in VISCP. These tools use the acquired data as a source to generate a flow diagram describing the evolution of the system. For example, using a virtual logic analyzer and following some rules on signal acquisition the evolution of a F.S.M. (Finite State machine) can be obtained.

Abstract:
In this paper the results are reported of functional design activities in the framework of the development of an electronic learning environment. The main function of the electronic learning environment is to support collaborative learning activities in problem based curricula. A review of literature in instructional design and related theories of learning resulted in the determination of a selection of basic instructional principles relevant for problem based learning. An analysis of educational practice was done based on reports. literature and a survey study among all students and teachers in two faculties. The results of this survey study combined with the results of a prior review of research outcomes in computer mediated communication for educational purposes, led towards the formation of the user requirements that are applied in the design of the prototype of the electronic learning environment. POLARIS will integrate tools for information searching, and processing, and a shared database that is used in asynchronous collaborative learning activities.

Introduction

The acronym POLARIS means Problem Oriented Learning And Retrieval Information System. The system to be developed can be described as an electronic learning environment in which the learner can find all the tools that can be used in collaborative learning activities between scheduled two-hour-meetings of tutorial groups that meet twice a week. The kernel of the system will be a shared workplace (database) in which learners report about the results and their progress in individual working on their objectives. Peers and tutors will be able to comment and edit these individual reports (asynchronous collaborative learning by groupware). The electronic learning environment will be accessible 24 hours a day, from the campus (LAN) as well as from the student's homes (TV-cable). The main functions of the system will be:
- supporting learning activities related to information: searching, processing and saving
- supporting the learning process.by communication tools [Ronteltap and Eurelings, 1996]

Principles in Instructional Design for Problem Based Learning

In the analysis of the basic principles in instructional design for problem based learning we connected three elements: knowledge, learning and instruction. In instructional design it is regular to connect the elements of learning and instruction: Instruction is seen as facilitating learning. Developments in instructional technology, however, lead to the awareness that assumptions about the nature and development of knowledge are the beginning of any theoretical foundation of instructional practice. The distinction between information and knowledge, and the emphasis on the social interactions in knowledge construction make constructivism relevant for applying information and communication technology in the teaching-learning process. From two perspectives we examined constructivist learning theories. From the perspective that knowledge is a constructed entity the activities that students perform were accentuated as well as the learnability of construction activities in itself. The third element in our analysis was the social context of learning. The following instructional principles were obtained:

1. The function of a learning environment for the learner is to work in a context where thinking is challenged and assistance is provided in order to become an independent learner, who knows that learning will continue.
2. Knowledge is acquired by active searching and processing of information, directed by experiences in an authentic context.
3. The subject of learning is of equal importance as reflection about the process of learning.
4. Learning is a social activity where individual understanding is the result of agreement about concepts in collaborative working groups.
5. Problem analysis is the stimulus for a self directed learning process, owned by the learner that promotes engagement.

Survey of Learning Activities

These principles of instructional design for problem based learning were the basic elements in the development of a questionnaire in which the actual learning activities of students were examined. The items of the instrument (90) were clustered to aspects of information related activities (searching, processing and saving) and communication activities, related to subject matter or learning process. The questionnaire was sent to all students. Also all tutors were asked to fill in the questionnaire in order to make a comparison between performed and expected learning activities. 671 students and 136 tutors participated in this study.
Summary of the main findings ordered through the learning activities in the instrument:

- *Information searching*: The curriculum as it is presented to the students is not effective enough in producing active and independent information search activities. Skills in information searching, and also the use of tools that are available in the library (catalogues, CD-ROM, Internet) were ranked at a lower level than might be expected.
- *Information processing*: Tutors expect a higher level of goal-orientedness in the learning activities of their students. Students in PBL-curricula do not develop a specific learning style.
- *Information saving*: Students save their information (texts and notes) systematically for later use. However, retrieval of it is often difficult.
- *Communication*: Communication after individual learning remains restricted to the content of learning, students do not report about the learning process. Students do not get individual feedback about their progress in the tutorial groups. Students learn from explaining the content of learning to their peers.

User requirements

The findings of the literature review and survey study were translated to the following user requirements:

- POLARIS must present facilities for an electronic tutorial group in which students and tutors can ask questions and submit answers, display results of learning and discuss these results.
- POLARIS, the electronic learning environment in which students can work collaboratively, must be available between the meetings of the tutorial group. This enables students and tutors to perform activities in the context of learning control.
- POLARIS should support students to access and retrieve information from diverse sources. Search tools must be part of the system to give support to students in their search process.
- POLARIS must support storing and accessing of information. Related to conceptual models of the users a framework has to be designed for the storing and access structure.
- There is a need for coaching by a tutor in the electronic learning environment.

The Influences of Cognitive Learning Styles on Computer-Aided Learning

Jonathan L. Ross

jross@acs.ucalgary.ca http://www.ucalgary.ca/~jross

Introduction

One of the most powerful features of computer-aided learning (CAL) is its capacity to individualize instruction to meet the specific needs of the learner. Self-paced instruction, the ability to present content in a variety of ways (e.g., text, video, sound, graphics etc.) and features such as hypertext make CAL a viable learning medium. The use of CAL in education has burgeoned in recent years. Faced with increasing class sizes and heavier work leads, teachers are looking towards CAL as a means of supplementing classroom instruction. In addition, CAL software continues to improve in its ability to engage learners and provide realistic and stimulating learning environments. Educators can now choose from a variety of educational software packages designed to augment the curriculum. However, as will be discussed in this paper, CAL may not accommodate all learners equally, a finding that may have significant implications for education and the future of CAL. Teachers should, therefore, remain cautious when using the computer as a learning tool.

The *Gregorc Style Delineator*

Designed to assess learning styles, The *Gregorc Style Delineator* is a self-scoring battery which focuses on two types of mediation abilities in individuals: perception and ordering. The two dimensions of ordering are referred to as sequential and random; the two dimensions of perception are abstractness and concreteness [Gregorc, 1982]. Gregorc combines these abilities to create four mediation channels of cognitive styles: concrete sequential (CS), concrete random (CR), abstract random (AR), abstract sequential (AS).

People who are dominant CS are usually practical, thorough, well-organized and prefer quiet, stable and structured environments. CS individuals tend to perceive reality as the concrete world of the physical senses and think in a sequential and orderly fashion. AS people consider themselves as evaluative, analytical, logical and prefer mentally stimulating, orderly and nonrestrictive environments. AR individuals are highly focused on the world of feeling and emotion and are sensitive, spontaneous, attuned, person-oriented people. Thought processes of AR individuals tend to be nonlinear, multidimensional, emotional, perceptive and critical. AR people prefer active, free and colorful environments. Finally, CR individuals process information in three-dimensional patterns and think intuitively, instinctively, impulsively, and independently.

Method

The primary purpose of this study was to determine the effects of learning styles on human-computer interaction. To investigate differences between participants, subjects received the same treatment. A CAL program covering 15 steps involved in performing adult Cardiopulmonary Resuscitation (CPR) was designed by the researcher and used to collect data. (The program is currently being marketed internationally to Nursing schools.) Seventy undergraduate volunteers from The University of Calgary (26 males, 44 females) participated in the study.

Independent Measures: The researcher used subjects' highest *Style Delineator* score as a measure of dominant learning style. The following is a breakdown of this study's participants according to dominant learning style group:

CS (20), CR (20), AS (14), AR (16). In addition, subjects' 20 question pre test score was used as an independent measure.

Dependent Measure: Learners were evaluated with a 20 multiple choice question post test.

Research Question: Do learning outcomes differ significantly based on subjects' dominant learning styles?

Results

Learning Outcomes: Results indicated that, as a group, subjects increased by almost two points from pre test to post test, and that means were significantly different between the two tests ($F_{(1,66)} = 57.91$, $p = <0.001$). To examine whether learning outcome differed significantly between learning style groups, a two-way ANOVA (2 X 4 factorial analysis) was conducted. The data revealed a significant dominant learning style by treatment interaction effect ($F_{(3,66)} = 20.11$, $p = <0.001$), indicating that there were significant differences in the magnitude and direction of achievement between the four learning style groups. The mean test scores revealed that three of the four dominant learning style groups showed gains from the pre test to the post test. The AS group increased an average of 3.64 (or 18 %), displaying the highest gain of the three groups. CS and CR groups increased an average of about 2 points (or 10 %). Interestingly, the AR group *decreased* from pre test to post test an average of just over 2 points (or 10 %).

Discussion

The literature suggests that dominance in CS and AS mediation channels predisposes the individual to having a preference for working with computers (be it in the capacity as a computer programmer, or as a learner using CAL software) [Butler, 1984] [Gregorc, 1985] . Randoms are said to find working with computers frustrating [see Gregorc 1985, pp. 202, 20]. In particular, AR individuals prefer human contact throughout the learning process, and prefer engaging in tasks requiring verbal and multidimensional responses [Butler, 1984]. Results from this study are consistent with results found by Davidson et al. [1992]. The researchers found that AR individuals enrolled in a computer applications university course showed significantly lower achievement levels than did the other three *Gregorc Style Delineator* groups. AS individuals showed the highest gains in the course, indicating their ability to work well with computer technology.

Conclusion

Computer-aided learning (CAL) has tremendous potential to provide teachers and industry with a powerful educational tool. However, educators must be cognizant of inherent differences which exist between learners--differences such as cognitive learning styles. Results from this exploratory study show that some learners may have difficulty adapting to computer-aided instruction. It remains essential, then, that the computer be used a tool for *supplementing* classroom activities, not supplanting them. The results from this exploratory study suggest that some learners (AR individuals) may need the support and guidance from the teacher, while others (AS individuals) may be able to learn from the computer relatively independently. Hence, teachers should not assume every student will automatically benefit from computers in the classroom. There remains the need for interpersonal contact and guidance to ensure that all students attain their learning potential.

DEVELOPING A PROFILE OF THE ONLINE TEACHING ASSISTANT

*Vivian Rossner, Simon Fraser University, Canada, vivian_rossner@sfu.ca

Denise Stockley, Simon Fraser University, Canada, dstockle@sfu.ca

*This paper was written collaboratively and order of authorship is not a reflection of contribution.

This paper presents results from the second phase of an ongoing study concerned with the pedagogical needs of online teaching assistants. In the initial phase (Stockley & Rossner, 1996) we interviewed a small number of graduate students teaching online, some for the first time. Their responses to a series of open-ended, experienced-based questions indicated that pedagogical issues pertaining to online instruction need to be identified and addressed. Based on these issues, it became apparent that there is an emerging profile of the online teaching assistant that has yet to be articulated. In this phase of the study, we expanded the pool of respondents in order to extend our database of information about their experiences and will use this data to develop a profile of the online teaching assistant. This profile includes information that addresses the following needs: access and technical training, pedagogical training including instructional planning, implementing appropriate teaching strategies, and evaluating the online student.

Initially, in the absence of well-documented studies, we framed the questions based on assumptions about online teaching derived primarily from anecdotal information available through student evaluation of the courses. Findings from the first study (Stockley & Rossner, 1996) demonstrated that our first assumption, that online teaching assistants had prior technical training, was unsubstantiated. Although, several of the online teaching assistants were familiar with the technology, none of them had received prior formal training before the onset of their course. Our second assumption was that these online teaching assistants were pedagogically prepared to teach online. In fact, they learned by doing. Further, we thought that prior traditional teaching assistant or tutor-marking experience would facilitate effective use of online teaching strategies. We found, instead, that all of the teaching assistants were highly successful teachers online regardless of both prior teaching experiences or familiarity with the technology. Finally, we assumed that attitude toward teaching online and toward technology would play a critical role in their perceptions of the online experience before and after teaching. This assumption was correct. We found that attitude did play a role with respect to the level of personal satisfaction gained or not gained during the course of online teaching.

Methodology

The data collection procedures for this study were identical to phase one, where we asked online teaching assistants to respond to a series of demographic and open-ended experience-based questions. Online teaching assistants were defined as those individuals who had not designed the course, were graduate students, were working under the supervision of a faculty member, and had taught at least half of the course in an online environment.

Participants were initially contacted by phone and then completed the interview questions through e-mail. The questions covered attitudinal transformation from the initial stages of working online through to the final stages of the course. The questions highlighted participants familiarity with the types of technology required and the time spent online. Of particular interest was how the teaching assistant organized the volume of responses received and how they provided substantive feedback to students. Further, we asked if they had advice for others and if they would do anything differently after their online experience. These responses gave the first indication of an emergent profile of the online teaching assistant that is distinct from the traditional conception of their work. The interview responses for this phase of the study were analyzed to determine what patterns of teaching practices emerged that made the online experience unique.

Discussion

This profile includes further analysis of questionnaire data collected from a larger sample of online teaching assistants. Their numbers are not large, but they are growing as more courses and programs offered via online instruction continue to increase. Consequently, the profile we derived from this study is unlikely to be static. Rather, it will undergo continuous revision in ways that address issues noted above concerning access, and technical and pedagogical training.

MAESTRO: Guiding Students to Skillful Performance of the Writing Process

Dr. Kurt Rowley and Melinda Crevoisier
Command Technologies, Inc.
USAF Armstrong Laboratory / HRTI
Brooks AFB, Texas USA
E-Mail: rowleyk@cobra.brooks.af.mil
E-Mail: crevoisier@cobra.brooks.af.mil

Abstract: *MAESTRO* is an adaptive writing process tutor for high school level English instruction. The principal factors influencing the design of *MAESTRO* were research results from use of the R-WISE (Reading and Writing in a Supportive Environment) writing tutor, field input from high school English teachers who had used R-WISE with their classes, cognitive research into the writing process, and the cognitive apprenticeship instructional strategy.

The use of computers to teach fundamental skills associated with the production of written text has been the focus of numerous studies in educational technology and applied cognitive psychology over the past 20 years. For example, Zellermayer and his colleagues tested a software writing assistant designed to provide students with writing strategy ideas and facilitate metacognition about writing, two important writing process skills. They found evidence that by using this facilitative software students were able to internalize the guidance and produce improved writing products [Zellermayer, Salomon, Globerson & Givon, 1991]. Similarly, Carlson and her colleagues tested a computer-based writing environment (R-WISE: Reading and Writing in a Supportive Environment) that focused on strengthening critical thinking skills associated with the writing process skills of goal-setting, generating writing ideas, and organizing those ideas into written text. They found that students using R-WISE outperformed control-group students on overall measures of writing quality and analytical reasoning skills, showing performance improvement of between one and two letter-grades [Carlson & Miller, 1996; Rowley, Miller & Carlson, in press; Rowley & Miller, in press].

The *MAESTRO* Design Factors

The *MAESTRO* research program is a follow-on to the R-WISE research with the goal of designing effective facilitative software that guides students to skillful performance of the *entire* writing process. *MAESTRO* uses advanced computer technology designed based on four primary factors: findings of the R-WISE research program, field input from high school English teachers who used R-WISE with their classes, cognitive research into the writing process, and the cognitive apprenticeship instructional strategy.

The first factor influencing the design of *MAESTRO* was previous research with R-WISE conducted with the U.S. Air Force's Fundamental Skills Training (FST) Program, a multi-year research effort to transfer advanced, adaptive training technology capabilities from Air Force technical training research, to public education. The R-WISE software was designed as an adaptive, supportive learning environment for several tasks associated with the writing process. R-WISE was tested and evaluated at 14 high schools in 5 different U.S. States over the period 1992-1996. The primary factors from the R-WISE research that influenced the design of *MAESTRO* were the general approach of the software to teaching writing skills through process visualizations, the designs of several goal-setting activities, and a brainstorming exercise called *Cubing*.

The second major factor influencing the design of *MAESTRO* was field input from teachers who had used the R-WISE software with their classes. Interviews with 25 teachers provided information about the perceived effects of various components of R-WISE on student writing abilities and system capabilities considered by the teachers to be important in the design of *MAESTRO*. The teachers identified as important the ability of *MAESTRO* to provide individualized learner guidance, to utilize a motivational strategy throughout, to allow for a high degree of teacher control over the tutor's operation, and to address the entire writing process.

The third major factor in the design of *MAESTRO* was cognitive research into the writing process. The major components of the writing process include goal-setting, generating ideas, developing a writing plan, translating ideas into text, and revising the text with regard to the original writing goals [Flower & Hayes, 1980]. All instruction, activities, and supporting advice in *MAESTRO* are focused on shaping the student's writing process toward an expert writing process. The student can navigate and perform work in 22 workspaces that simulate tasks performed by the expert writer. *MAESTRO* monitors the student's use of the workspaces in order to determine the level of mastery of the writing process achieved by the students, and provide relevant coaching and advice.

The fourth major factor in the design of *MAESTRO* was the use of a cognitive apprenticeship instructional strategy to help students develop writing process skills in the context of regular writing work [Collins, 1988]. The cognitive apprenticeship strategy used by *MAESTRO* includes using instructional modules to teach tactics and heuristics necessary for proper task accomplishment, sequencing the availability of workspaces from simple to complex based on student writing process mastery, situating the learning and practice in a realistic writing prompt context, using examples to model proper skill performance, and gradually fading the coaching as the student gains competence.

Software Architecture of *MAESTRO*

MAESTRO was written in Multimedia ToolBook 4.0 (Asymetrix) using the Paradox database (Borland). The software was designed using principles of object-oriented programming and an open-ended architecture. The object-oriented design makes the system generic in the sense that the controlling module does not reference specific workspaces by name, but accesses instructional resources based exclusively on rules. The rules allow the tutor to produce individualized instruction, by comparing the student operation of the workspaces with a model of the expert writing process. Because of the object-oriented design of the software, each module within the tutor operates completely independently from the others, sharing only high-level information related to the rules.

Testing and Evaluation

MAESTRO is being tested at 24 middle and high schools in Texas, New Mexico, Ohio, New York, and Pennsylvania during the 1996-97 school year. The current experiment will measure the effects of the tutor on individual student writing products. Ongoing research will identify organizational and implementation issues related to the adoption of the technology by public schools, and provide information on the utility of the design factors as implemented the classroom environment.

StreamWorks for Distance Education

Ioan ROXIN, GRACIMP, INSA Lyon, 20, Av. A. Einstein, 69621 Villeurbanne, France, roxin@if.insa-lyon.fr
Nabil AKROUT, Xing Technologies, 1540 West Branch Street, Arroyo Grande, CA 93420, nakrout@xingtech.com

Abstract :
The technology revolution in education has already begun. Multimedia, World Wide Web (WWW), video and telecommunications technologies, computer-based simulations, distance learning are a familiar sight in most schools. With a hypermedia environment the role of each element in education field (teacher, student, content) is changing. Many universities use **IRC** (Interactive Relay Chats), **MUDs** (Multi-User Dungeon), **MOOs** (MUD Object-Oriented), listservs or plain email for class discussion and interaction. This paper proposes the concept of ®StreamWorks, the multimedia client/server architecture, which is developed by Xing Technology Corporation. ®StreamWorks is for world-wide and local network delivery of live and on-demand audio/video.

Keywords : Distance education ; ISDN ; Live and On-Demand Audio/Video ; Multimedia system ; Video data compression.

Introduction

Far from being a revolution - as frequently described by the press - multimedia is opening hard and software to new forms of information display, other than text and graphics. We witness the utilization of new media: sound, images, video and, in general, everything that can be digitalised. As a matter of fact, multimedia is neither a new technique nor a specific area of computer sciences. Technical innovation is connected to the possibility to unify production, storage, treatment and transport of all kind of information using the same technological basis represented by digitalization.

Video has become one of the most important media in multimedia applications. Existing "on-demand" multimedia (video) network architectures are based on tightly coupled point-to-point client-server communication, which result in 4 major limitations:

1. significant interaction is required between client and server for flow control, requiring complex server programming and significant data overhead (on the order of 25% - 50%);
2. servers are not designed to deliver the same streams simultaneously to multiple users, making "live" delivery to multiple users impractical;
3. LAN-based server architectures are not designed to operate over wide area networks;
4. communication protocols employed are proprietary, and do not directly support the TCP/IP standard.

StreamWorks represents a significantly different multimedia network architecture, based on the concept of "*streaming media*". This architecture supports both "on-demand" as well as "live" video and audio delivery (in real-time, without having to download first the audio or video file to a local disk drive) which does not require close coupling between the client and server. It easily supports "*multicasting*" and "*unicasting*" of live or on-demand content to multiple simultaneous users over local as well as wide area networks.

StreamWorks Applications in Distance Education

Studies on interactivity showed that a human being can remember only: 10% of what is read; 50% of what is seen and heard; 70% of what seen, heard and read. Accordingly we may say that one of the main multimedia markets is education and training. By his essence and senses the human being is multisensorial, i.e. multimedia. So it is not surprising that today's most used multimedia applications concern education and training.

Research on delivery modes and their correlation to student achievement outcomes has shown that students learn better via teletraining mode than face-to-face instruction [Chute, Balthazar and Poston 89, TFDE 93]. A multimedia educative application considerably strengthens the impact of the studied subject and the interest of the students. The students must take more responsibility for, and be more active in, their learning - whether that means attendance at a satellite downlink site, participation in a class listserv, or delving deeper into a WWW-based lesson.

Due to the development of the intreactive and audiovisual networks, distance education became a reality in schools and universities. The tele-lecture ensures the network distribution of voice, sound and documents. Teaching is dispensed of a particular site and diffused in a lot of other places knowing that interactivity between the sending place and the receiving one is possible. ®StreamWorks is a good solution for distance learning.

Technical Description of ®StreamWorks [Gordon 94]

StreamWorks was developed as a client-server media distribution architecture which can operate independently or complement existing WWW HTTP/HTML architectures on local area networks, private data wide area networks and public data wide area networks (e.g. Internet).

Streaming of multimedia data is a significantly different way of delivery, as the user can view/hear the data as it is being transmitted instead of waiting for file transfer completion, and there is no requirement for complex file systems such as Netware or NFS. In addition, StreamWorks uses standard TCP-IP network protocols, and takes advantage of new "multicast IP" protocols for data delivery, allowing multiple users to simultaneously view/hear the same data streams without duplication of data or use of intrusive broadcast protocols. A typical StreamWorks configuration will include some of the following components: StreamWorks Network Encoders; StreamWorks Network Servers; StreamWorks Network Clients; StreamWorks Network Manager.

The benefits of StreamWorks are : compatibility with existing enterprise TCP/IP networks, including Ethernet, ATM, FDDI, ISDN, T1 and Frame Relay; additional live and on-demand video and audio services to private and public WAN's and LAN's without infrastructure changes; low overhead (3-5%) video and audio streams are fully routable; all network components are SNMP manageable; network congestion is controlled by on-the-fly bitrate reduction of video and audio streams; streams are scaleable from full rate down to ISDN BRI (56-128kbps) and below (as low as 8.5kbps with LBR audio); SQL database management of StreamWorks streams; servers may be distributed for load balancing and stream caching; software-only and hardware accelerated video and audio decode provided on client systems; user interface customizable through HTML/HTTP interface; compressed video and audio streams compliant with MPEG-1 and MPEG-2 standards.

StreamWorks is ideally suited for ISDN remote access server and regional server applications such as distance learning and news delivery, through its ability to provide on-the-fly MPEG stream bitrate reduction and service of large numbers of simultaneous users. Xing is currently developing a reference platform for ISDN regional servers which delivers both high resolution / low frame rate as well as low resolution / 30 frame per second video streams.

Applications requiring "media on-demand" benefit from StreamWorks's simplified approach. The advantage becomes most apparent in applications with a combination of "on-demand" and "live" media delivery requirements, especially when the clients are geographically dispersed[1]. Although commercial broadcast services provide very visible and compelling examples for Xing's capabilities, the largest volume applications for *streaming media* will be in corporate, educational, government and health-care networks with "on-demand" and "live" communication requirements, including training, presentations, and occasionally, entertainment.

Conclusion

®StreamWorks is a development stage architecture that uses a distribution technique to deliver an advanced information management system for broadcasting industry, tele-education and telemedicine. The challenge of ®StreamWorks in teleservices is to enable equity of the quality of services of Telecommunications and Information Technology to citizens in less favored regions, like India or China, where the quality of services varies greatly by region, but where there are some very current communications facilities and infrastructures. New applications are being developed with StreamWorks for distance learning, corporate communications, news delivery and computer based training in corporate, educational, government and health care markets, employing wide area, local area and ISDN networks.

[1] NBC and Reuters are using StreamWorks to deliver multiple simultaneous live financial and news video broadcast channels to financial market subscribers (money managers, stock brokers, financial analysts) in cities throughout the US and Europe as part of their respective "NBC Desktop Video" and "Reuters Financial Television" services. Xing is developing similar delivery services for other commercial TV and radio programmers.

Creating a Virtual Integrated Learning Environment (VILE)

Malcolm Ryan, School of P.C.E.T., University of Greenwich, London. UK
E-mail: M.Ryan@greenwich.ac.uk

Gary Culwick, Academic Development Group, University of Greenwich, London. UK
E-mail: G.Culwick@greenwich.ac.uk

Abstract: The increase in off-campus programmes to deliver continuing professional development (CPD) in the higher education sector in Britain has resulted in a growing interest in the use of computer mediated communication (CMC). The use of E-mail and asynchronous computer conferencing to support distance learners is not a new phenomena and the benefits are both recognised and widely reported. [Kaye, 1992] [Mason, 1994]. The writers have adapted the basic desktop provided in Lotus Notes and created a community in which students interact and collaborate at a distance. This paper reports on the development of the Virtual Integrated Learning Environment (VILE) which facilitates an enhanced mode of distance learning.

Introduction

Recent developments in communications infrastructures have resulted in a global technological revolution [Tiffin & Rajasingham, 1995]. The media hype which has accompanied the exponential growth of the Internet with its highly visual point and click interface, multi-media 'plug-ins', synchronous chat and real-time video has somewhat overshadowed the humbler asynchronous media.

Asynchronous versus Synchronous

There is no doubt that the Web is both attractive and powerful but by its very nature is a technology driven environment in a constant state of flux. Programmers, designers and networking specialists are probably able to harness the power of this technology and create highly complex learning environments but such a range of knowledge and skills is likely to be outside of the experience of even the reasonably computer literate educator.

The attraction of a synchronous medium can not be denied but there is evidence to suggest that asynchronous technologies are better able to facilitate the reflective models [Mason & Kaye, 1990] embraced by many CPD programmes. Additionally, the time-location independent nature of asynchronous media [Harasim, 1989] may facilitate greater flexibility and student autonomy. Furthermore, many adult distance learners engaged in CPD programmes are known to study at home and accessing the Internet would normally require them to subscribe to a commercial service. To benefit fully from time-location independence, students should not be required to work synchronously and in the current financial climate they should not have to bear the additional costs incurred by working on-line or paying subscriptions to Internet providers.

The Virtual Learning Community

Adult distance learners place a high value on regular access to tutors and their peers and they benefit from a sense of belonging to a learning community [Gould et al, 1996]. A recent Enterprise in Higher Education (EHE) funded pilot project which examined the use of CMC in support of adult distance learners, utilised the concept of a virtual learning community. This concept is based on the principles of peer exchange, collaborative learning, enhanced access to tutor support and flexibility. Project staff evaluated a number of CMC software products but discounted many because they either resembled a bulletin board environment providing electronic messaging but no sense of a community or there was no facility for off-line working.

Several colleagues had personal experience of working with command line, text based systems such as CoSy and Caucus but considered them to be quite difficult to master and not very appealing.

The software eventually chosen to deliver this concept was Lotus Notes, a well respected and tested groupware product described by the originator as an application development environment. Groupware is essentially any computer application that runs over a network, and/or is accessed by direct dial means, allowing the user group to increase their communication, collaboration, and co-ordination. Lotus Notes is currently one of few products on the market that captures the three main areas of communication, collaboration and co-ordination in one product, and adds to this the ability for customization.

The immediate advantages of Notes appeared to be its availability on multiple platforms in both server and client forms. It is an industry-standard package with a massive international user base providing sophisticated E-mail and conferencing facilities. It appeared fairly easy to operate on the one hand and would appeal to novice users of communications technologies but with infinite possibilities for expansion and development. It was supplied with a number of templates which were customisable to facilitate the development of a range of databases to support conferencing and workflow applications. Unlike many of its competitors, Notes facilitates off-line working with *replicas* of conferences and mailboxes using a remote, direct dial facility with the option of networking and connectivity via TCP/IP.

It was perhaps this apparent ease of use, the attractiveness of the interface and the facility to work completely off-line which appealed most. Using the installation disks as supplied a Notes server and several clients were very quickly established and working perfectly across a Novell network and by remote dial in access using standard modems. A number of trial conference databases were created using the supplied templates and testing of the system began. The setting up of the server and clients was accomplished with a minimum of technical knowledge. The only requirement was for a computing technician to install and configure a card to connect the Notes server to the university's Novell network.

Developing the environment

The original development team of four consisted of three teacher educators who regularly used Windows based products on PC compatible computers, and a resource-based learning development officer. Our initial use of Notes was simply to provide an e-mail and conferencing facility for geographically dispersed students who would be working from their homes.

As the team began to plan for the use of the system by students we identified a number of activities that we would want to support. Printed materials containing in-text activities for each of the units on the programme of study already existed. We decided to use the discussion template to create a conference database for each of these units, tutor group databases and a discussion area for the development team. The same template was used to create a Cafe for social chat, informal exchange of ideas and as a relatively safe area in which both students and staff could practice their conferencing skills. The document template enabled us to create a database where training materials on the use of the system might be stored and accessed by all users. After an initial period of operation another database was created to act as a Notes Help and Advice Centre where common problems and issues to do with the use of the system could be handled.

Unique Features of CMC

The pilot project operated for one year, a number of refinements were made to the system and we began to change the way we approached the delivery of and support to distance learning. Initially, we tried to reproduce our experiences of classroom-based teaching but recognised that computer conferencing impacts significantly on the dynamics of the group and changed the nature of face-to-face (F2F) activities. Additionally, we began to realise that communications technologies provide some unique opportunities for interacting which it would be to everyone's advantage to exploit [Anderson, 1996].

In particular we noted that students welcomed twenty four hour access to the learning community and that the archiving of all discussion produced a much valued resource. These two features alone establish a novel identity for CMC supported distance education in that neither aspect is available in traditional F2F or distance models of learning. The richness of the archived exchanges between participants aided the reflective process and students gained considerably from access to a team of staff who were able to provide different perspectives on issues and problems. There were far more opportunities for students to determine the pace, direction and focus of discussions leading to a more learner-centred approach to distance education when compared with the pre-prepared texts that had previously supported the programme.

Based upon what has been learnt we have now developed a customised Notes desktop with databases that combine together to give the impression of a virtual community. By employing selected aspects of the Lotus Notes applications development environment and exploiting the unique features of asynchronous CMC we are able to support innovative forms of teaching and learning at a distance.

VILE

This new Virtual Integrated Learning Environment (VILE) consists of classrooms where a range of activities and discussions occur, an electronic resources centre to which both staff and students contribute, a tutor-free student common room for social chat and virtual coffee, a staff room for on-going curriculum development meetings, a mail room and an advice centre. VILE supports a new mode of distance learning which possesses some distinct advantages over both traditional and synchronous models. This new environment is currently being used to deliver three CPD programmes. There are plans to conduct a number of action research projects to examine in more detail the significance of the impact of CMC on distance education. We intend to exploit the unique features of CMC in the design of new curricular and to further develop the concept of VILE.

Exploiting Groupware Reveals an Enhanced Distance Paradigm

Malcolm Ryan, School of P.C.E.T., University of Greenwich, London, UK.
E-mail: M.Ryan@greenwich.ac.uk

Abstract: A recent pilot project at the University of Greenwich in London reported that employing groupware in the form of Lotus Notes was able to provide a technological solution to some pedagogical problems. It enabled adult distance students to study within an enhanced Time Location Independent (TLI) context with opportunities for regular peer and tutor interaction, collaboration and reflection [Gould et al, 1996]. This paper outlines the reasons for using groupware on an existing distance programme, presents some student and tutor feedback, compares aspects of the system employed with traditional distance and face-to-face (F2F) models and postulates an enhanced distance paradigm.

Context

The project involved adult students engaged in an in-service teacher education programme operating at a distance. The programme was previously delivered using a traditional model involving printed materials containing in-text activities, occasional study days at a central location and telephone tutorial support. In common with many programmes based on this model there are few opportunities for peer interaction or collaborative learning, little sense of belonging to a group or institution and contact with tutors may be erratic and at times difficult [Ryan, 1994].

The model of in-service teacher education favoured by the School of Post Compulsory Education and Training (P.C.E.T.) is based upon a series of interactive opportunities that enable learners to engage in *reflective conversations* [Schon, 1983] and demonstrate progression through an experiential learning cycle [Kolb & Fry, 1985]. Interaction, the sharing of expertise and peer tutoring are considered to be essential ingredients of a programme based on the concept of the reflective practitioner but independent, distance study removes many of the interactive elements of professional learning implied by the reflective practitioner model [Kolb & Fry, 1985].

Computer Mediated Communication (CMC)

An earlier report [Ryan, 1994] had suggested that computer mediated communication (CMC) might address the shortcomings of the traditional distance model by providing an environment in which individual students could interact, providing a collaborative forum for the reflective conversations and improved access to tutors. We believe *interaction* to be one of the key features of CMC because, "where opportunities exist for interaction in learning situations at a distance, it helps learners to make leaps in their understanding that are unlikely to occur when working in isolation". [Owusu-Sekyere & Branch, 1996a] We also agree that, "The asynchronous, text based format of computer conferencing offers a better opportunity than the other conference media for reflection on participants' contributions ...." [Laurillard, 1993] and chose Lotus Notes, a *groupware* product utilising a database structure which combines the functions of communication, collaboration and co-ordination.

The facility within Notes to develop an integrated learning environment using a range of purpose-built databases provides a structured and secure virtual learning environment in *replica* on every student's computer so they may interact with it and other users as often as they wish without the need to connect to a remote server.

Unique Features Emerge

Initial feedback from students indicated that they welcomed the opportunity to exchange ideas with their peers and appreciated being able to ask for and receive almost immediate support from tutors, twenty four hours a day. Additionally, students reported that they felt they got to know their peers and tutors and recognised personalities despite most communication being mediated by computer. In evaluation questionnaires they wrote about feeling as if they were actually attending the institution and made reference to being part of a *learning community*.

Where these distance students made regular use of the system both their ability to reflect on actions and to communicate these reflections in writing were greatly improved. The facility to work entirely off-line on *replicas* of conference databases was considered to be a considerable advantage. The archive of conference entries, which was hierarchical, threaded and indexed, also provided the students with a valuable resource which it is believed further enhanced opportunities for reflection. Combined with twenty four hour access to the learning community these students were able to benefit from features not present in either traditional distance nor F2F modes of delivery.

Another unique feature of this CMC enhanced distance model was the potential for two tutors to *team teach* a unit. This provided opportunities for students to receive inputs from two different perspectives and for the staff concerned to collaborate and support one another. Tutors were able to be more responsive to student needs and questions as they arose making the discourse more *student-centred* and needs driven than in a traditional model of distance delivery.

Feedback from the tutors indicated that they felt as though they were managing a group of students as in a F2F class rather than a number of individuals as is usually the case within traditional distance tutoring. Patterns of interaction closely emulated those found in F2F classrooms [Owusu-Sekyere & Branch, 1996b] with the added advantage that students and staff did not have to be physically present nor connected to the system at the same time as would be the case with synchronous conferencing.

Models Compared

Traditional distance learning involving the use of printed materials and telephone tutorials is known to be an isolating experience for many students as there are rarely opportunities for on-going access to or collaboration with other learners and the tutor. Consequently, there is little discussion and team teaching is not possible except insofar as materials may be the product of more than one tutor. Such a model of learning is deficient in those particular attributes most needed to support the preferred approach to in-service teacher education expounded by P.C.E.T.

If one compares CMC with F2F teaching it is evident that it provides some opportunities not found in the physical classroom. The latter tends to operate to a timetable (time/location dependent), can usually not provide participants with sufficient time to reflect on learning and whilst quality discussion may take place it is usually transitory in nature as no recording device is normally used to capture student exchange and tutor input.

In this pilot project it appeared that applying CMC to an existing traditional distance model of teacher education has enabled students to interact with tutors and peers, feel part of a learning community and use the archived conference material to enhance the reflective process. They have been exposed to team teaching at a distance and to opportunities to collaborate. The content and pace of the curriculum has become more student-centred and all within a context which is Time-Location Independent. There are sufficient unique differences between CMC and traditional distance models to suggest that what we have observed in action is an enhanced paradigm of learning [Harasim, 1989] in which the novel features are related in part to the CMC system adopted.

Conclusions

Our experience suggests that exploiting groupware has revealed a CMC enhanced model of distance learning which appears to address the pedagogical problems formerly encountered when a traditional distance model was employed to deliver in-service teacher education. In addition it has provided students and staff with some unique opportunities that do not exist in either traditional distance nor F2F modes of delivery currently used within P.C.E.T

It is recommended that these unique characteristics be explored and exploited to further enhance the experience of students engaged on distance teacher education programmes. It is further suggested that this enhanced paradigm may provide opportunities for off-campus learning that were not previously thought possible within a traditional model of distance education.

Josephine To, Science Systems and Applications, Inc., USA, joto@wam.umd.edu

Introduction

Today's action-packed computer games captivate students in grades K-6. Young students demand fast-paced games that deliver high adventure, plus exciting audio and visual stimulation. Future educational software will have to compete for the attention of this especially demanding audience. Fortunately, we have the answer in interactive multimedia (e.g., images, text, animation, audio, video). If done right, educational multimedia can grab and hold the attention of these youngsters as effectively as computer games.

Our objective is to test the ability of multimedia to enlighten elementary school students about remote sensing. Elementary school is a critical time for students to form opinions about science. The language and content of educational software for older students are often inappropriate or unappealing to younger students. We hope to use multimedia to accomplish captivating a student's attention while applying the science to real-world applications. Combined with multimedia, science taught using images of the earth and planets attained by remote sensing can grasp the attention of elementary school students. Geography and earth science lessons can be powerfully reinforced through satellite images. Students can view damage from floods, volcanic eruptions, and droughts. Muddy drainage into lakes, resulting from poor agricultural practices, and deforestation are all discernible from space. An effective multimedia package can complement the science curriculum by providing a context to real-world applications.

One of NASA's stated goals is to support general education by distributing information obtained from its scientific missions both to schools and to the general public. Dramatic images, graphics and video from NASA can play a powerful role in introducing young students to real-world applications of science. Our interactive multimedia package for elementary education in earth and space remote sensing will contribute to these goals.

Background

A prototype software package, created using Hypercard, was discussed by Masuoka et al., 1996. This prototype has been reviewed for content and approach by several teachers. These teachers have expressed an interest in using the package in their classrooms and have suggested ways to make it even more useful in complementing their lesson plans.

Our interest of appealing to a younger audience led us to develop a second software package geared toward elementary school students. A different multimedia authoring tool, Macromedia Director, was chosen to create a more sophisticated package. The current prototype is the basis for an elementary level multimedia package under development. The topics covered in the package will be:
How are remotely sensed images obtained and what are their characteristics?
What are the physical features being observed?
What are the issues that are being addressed through remote sensing?

Developing the Multimedia Package

Developing the multimedia package requires expertise in diverse fields. To achieve this, our team consists of remote sensing experts, educational experts, and interactive multimedia experts. To address the attention span issue, the package must go beyond the electronic multiple choice tests and slide show formats typical of many educational programs. The primary challenge in developing the package is recasting the scientific information provided by remote sensing experts to an elementary school level which can be incorporated in the classroom.

Teaching using multimedia has few resemblances to traditional teaching methods. Most curricula are structured in a linear fashion – each lesson building upon the previous. Multimedia is by nature non-linear. Non-linear methods can create an interactive environment appealing to the different modals of learning. This non-linear, interactive approach must be structured carefully because while grasping their attention, it can also divert the student from the desired task. Our package will provide short linear lessons via video and animation incorporated within a broad interconnected pattern of information. The interactivity and the ability to add alternate explanations or stimuli, without cluttering the content, is one major advantage multimedia has over traditional textbooks or videos. Such a package can function one-on-one, as well as providing visual elaboration of complex concepts for incorporation into a teacher's more formal lecture.

The multimedia program is being developed primarily using Macromedia Director. Images are obtained from researchers and from donations from private companies. Elementary school earth science curriculum is used as a reference to incorporate the package into the classroom. The resulting package is tested periodically during development to obtain feedback from teachers and students and to ensure desired performance.

Description of Package

The package will focus on three main areas: 1) what remote sensing is; 2) understanding light; 3) real-world applications. First, will be a broad overview and a definition of remote sensing. Why remote? What can remote sensing show us? A problem solving activity using images will reinforce the comprehension of remote sensing. Second, an understanding of the fundamental properties of light is needed to understand how remotely sensed images are obtained. Activities will include experimenting with filters, and an on-screen simulation of photography. The third area is broken down further and looks at real-world applications using different forms of remote sensing. The activities will use specific examples prompting the interpretation of data, recognition of patterns and problem solving. These examples also give context to specific science disciplines such as geology, biology, astronomy, cartography, hydrology, and glaciology.

Each concept will be approached using a similar sequence. First, relating the concept to the student's existing knowledge base. Each remote sensing concept will be explored using video, graphics, and animation. The next step is an interactive excercise which will evaluate their level of understanding. If the response is correct, a special activity will follow. An incorrect response will prompt an alternate explanation instead of reiterating the previous ineffective sequence.

Future Plans

The remote sensing multimedia package will be completed in the coming year. The final package, including a teacher's supplement, will be distributed to schools at cost on CD and for free on an ftp site. Portions of the package will also be converted to HyperText Markup Language (HTML) format for our World Wide Web site.

Telematic Learning Environments as an Alternative to Promote Deafs' Communication

(1) Lucila Maria Costi Santarosa
(2)Alvina Themis S.Lara (3) Maria Lilia Dias de Castro
Center of Informatics in Special Education
(NIEE-PRORHESC)
Federal University of Rio Grande do Sul - Brazil
E-Mail:lucila@cesup.ufrgs.br

Abstract: The possibility to create "virtual classrooms" or "virtual schools" which Internet, allows to break the isolation of those who due to physical and social barriers are forced to interrupt their education due to lack of special schools which provide them possibilities to a continuous personal and professional growth. This work focuses the potential of computer network using the philosophy of "learning to communicate and communicate to learn" investigating ways to use such resources with deaf ' youngsters. In the cyberspace we have created an environment of telematic learning to promote the communication among such students within our country (Brazil) and people abroad. The interchange of information through dialogues, discussion about topics of particular interest, the construction of cooperative material, among others, have taken place, and have as their main objective to develop the linguistic competence in writing. We here present this experiences and some observed results.

At the entry of the new century we live in a society very strongly information oriented. The most important things until now used to be to own and to control information. Nowadays, however, other aspects more related to the updating and to the speed with which the production and interchange of information are emphasized. Within this context, we seek for media support, and consider telematics one of the most powerful ones. The use of informatics and telecommunication together is transforming the world into a global village and changing the concept of society.

Due to the kind of communication and access of information that is occurring - the so called *"telematic culture"*- we seem to be walking towards new concepts and values including *"countries without frontiers"*, *"democratization of information"*, *"socialization of knowledge"*, among others.

In this same direction, the meaning of educational institutions have also changed. *"Virtual schools"*, *"virtual classrooms"*, *"virtual educational centers"* have appeared, openning new educational possibilities, even to those who are not able to be physically enrolled in the conventional school system.

This new context offers a very important perspective for the handicapped. The importance of such technology for the special education area has been highlighted. Special education is pointed out as being the most impacted area by the tehcnological advances and applications which are taking place as attempts to meet the specific needs of individuals with mental, physical-sensorial and motor limitations or deficiencies. Such applications are promoting changes in the social and affective dimensions of the individuals.

Part of our work, which is all related to the use of Information and Communication Technology in Special Education, focuses the potential of computer network using the philosophy of "*learning to communicate and communicate to learn*". At this moment, we are investigating ways to use such resources, specially the electronic mail, with deaf children and adolescents and cerebral palsied youngsters. In the cyberspace and using the "windows to the world" metaphore, we have created an environment of telematic learning including resources to promote the communication among such students within our country (Brazil) and people abroad. The interchange of information through dialogues, discussion about topics of particular interest, the construction of cooperative material, among others, have taken place, and have as their main objective to develop the linguistic competence in writing.

The possibility to create *"virtual classrooms"* or "*virtual schools*" which Internet makes possible, allows to break the isolation of those who due to physical and social barriers are forced to interrupt their education due to lack of special schools which provide them possibilities to a continuous personal and professional growth. This situation does not allow them to become integrated and to be productive in society.

Using a learning telematic environment in our Center , we carry out studies and experiences which aim to explore the telematic network resources with handicaped. We here present more specifically the work with deaf children and youngsters which emphasizes the interaction/communication process involved in the interchange of information and the cooperative production of written material (such as telematic newspapers, cooperative stories, messages among pen-pals).

The *objectives* of such work are:

(1) to study the possibilities of telematics, particularly electronic mail, in the communication and interaction process among deafs;

(2) to develop alternatives of interaction/communication and to give access to information by promoting the interchange of messages among deafs in Brazil and abroad. The main aim is the production of cooperative materials in a telematic learning environment;

(3) to develop intervention strategies involving writing, related to the communication difficulties of deafs;

(4) to observe and evaluate the effects of the telematic learning environment on the process of interacion/communication and the production of information of the deafs.

The study involved nine deaf students from different schools of Porto Alegre, the state capital, between 9 and 24 years old.

The students attended our lab once a week and worked during three hours. Observations of 18 months of work were recorded.

The activities involved access to Internet, initially in text form using the Telix system and later, using the graphic environment through Netscape. In addition to the access of information allowed by these systems, we emphasized writen production strategies using mainly: electronic mail - interchange of messages with virtual friends with or without any hearing loss, in Brazil and abroad; Telematic Newspaper - the creation of a newspaper containing texts of the deafs' daily lives; Story Book - an interactive story book containing collaborative stories written by our group of students and by students with special educational needs from Portugal. One of the students would write the beginning of the story (a brazilian or a portuguese student) and another friend would write the end of the same story.

Thus, support linguistic strategies related to aspects such as expression and content were used.

As summary we can point out improvements in some aspects.

In the *linguistic domain*, for example, the students:

(1)attained a satisfactory level of written expression since they were able to produce more coherent and cohesive texts;

(2)demonstrated more practical knowledge about phrase structure, which involves: adequate elements' order; verbal time; adverbial pronouns; verb and noun concordance; use of prepositions ; correct punctation.

In the *cognitive* perspective the students:

(1) presented improvements in their interpersonal relations, interchanging information and personal experiences;

(2) were able to express feelings and sensations, through writing; presented higher levels of autonomy, initiative and self-confidence.

In the *socio-affective* dimension and related to the cognitive aspects mentioned above, the students:

(1) attained higher levels of comprehension of the written messages ;

(2) were able to interpret the ideas expressed in the texts;

(3) were able to see other points of view besides their own;

(4) were able to identify errors and tried to correct them;

(5) made more associations, inferences and antecipations

What we here present is a very brief summary of the development of the deaf individuals whom we worked with. As we mentioned before, the focus of our observations was the interaction/communication process in a telematic environment and its possibilities to contribute in the deafs' development in the specified dimensions.

Over all, our observations suggest the importance to construct communication/expression interactive means and situations which may promote cognitive and social-affective dimensions for this special population.

We work towards minimizing the existing discrimination of this population, which is still very strong in our society, perhaps more in the so called third world countries. We also try to create and think of alternatives which can be carried out in "virtual schools and virtual classrooms", which can offer interactive opportunities with other people and access to information through "windows to the world" and aiming to enhance self-education.

Technology Integration in Collaborative Writing

John R. Savery, Ph.D.
Academic Technology Development
DePaul University, Chicago, U.S.A.
jsavery@condor.depaul.edu

This study of technology integration in collaborative writing took place in a required sophomore course called Business Communications. Weston and McCloud, the two instructors who re-designed and implemented this course, had corporate work experience to compliment their 17 years as university lecturers. Their re-designed course stressed a business-like environment and set the expectation that student generated business writing would be at a level acceptable in an authentic corporate environment. Students were treated as adults and expected to be responsible, self-directed learners. They worked in collaborative teams and utilized the available computer technology to produce written responses to problem situations. The four classes (fifty students each) met every Monday and Wednesday for 75 minutes in two connected computer labs. Each lab had twenty-five networked PCs, a laser printer, comfortable office chairs, and the usual florescent lights, utility carpet and neutral colors. The use of technology to support collaborative writing was part of a learning environment that included an extensive instructional simulation, collaborative teams, team teaching, and problem/project based learning activities.

Instructional Simulation - An instructional simulation of a multinational corporation (Starr Corporation) organized the course, provided a realistic business atmosphere and a context for the writing projects. Students were "hired" into the corporation and received an Employee Handbook with detailed information about the corporation and also served as the course syllabus. To ensure that all students began with a basic knowledge of word processing, spreadsheets, a graphics program, e-mail, and Internet browsers, the new employees were provided with training sessions (intensive workshops) on these business applications. Students were assigned to teams by the teachers, and teams rotated through a variety of departments within the organization to learn about various aspects of the corporation including; Marketing, Accounting, Purchasing, Human Resources and Operations. In each department, the teams received information related to the functions of the specific department and were tasked with producing an appropriate written response to the problem situations being presented. These assignments addressed the four primary types of business communications: routine, good news, bad news and persuasive letters or memos in the context of each department. From a theoretical perspective, the Starr Corporation simulation provided a larger context for the writing assignments (Honebein, Duffy, & Fishman, 1993; Savery & Duffy, 1995) that made the learning activities more authentic and meaningful for the students. From a technology perspective, all assignments were designed with the expectation that the computer technology would be utilized as a productivity tool.

Collaborative teams - The teachers assigned individuals to teams that were balanced along several key criteria - gender, part-time work responsibilities, prior business experience, leadership abilities, computer expertise, and several secondary criteria. (Kagan, 1992) Teams typically consisted of five (5) members that remained together for the semester. Individual students shared the grade for all team assignments such that 60% of an individual's grade was obtained through teamwork. This shared grading strategy was an important design component as it promoted a high degree of goal interdependence and resource interdependence (Johnson & Johnson, 1990) and produced many examples of mutual support, peer tutoring and team members holding each other accountable for incomplete tasks, tardiness, and missed classes.

Team Teaching - Neither teacher lectured during class sessions choosing instead to coach and mentor individuals and teams. Both acted as tutors and provided context (problem) specific coaching and extensive modeling of the metacognitive processes used by experienced writers. The teachers were generally able to provide individual students with the amount of cognitive scaffolding required as they developed their individual abilities and moved to teacher-independent behaviors.

Problem/Project based approach - Teams had four class sessions in which to produce written responses to the problem situations. Student teams became proficient at assigning tasks, coordinating efforts and completing the project within the time specified: project management skills seen as beneficial learning outcomes that complimented learning the core content of effective business writing. The project based approach allowed teams to improve from one project to the next by incorporating teacher feedback, comments and grades. The use of realistic problem scenarios encouraged students to go beyond the information provided (see Bruner, 1973; Perkins, 1993) and utilize their higher-order thinking skills. (Barrows, 1992; Barrows & Myers, 1993) The writing assignments required students to extend their skills and knowledge with computer applications, e.g. Accounting required the team to prepare a Payroll Report (spreadsheet) for the entire class, Marketing, required the team to prepare a multi-column promotional brochure that included graphics.

Integration of Technology with Collaborative Writing - Collaborative writing as described by Saunders (1989) contains a range of interaction structures that combined with the tasks assigned produced four primary categories of collaborative writing activities: co-writing (most collaborative form), co-publishing, co-responding and co-editing (least collaborative form). All four teams in this study used the co-editing format consistently with isolated examples of co-writing. Co-responding was the dominant form of collaborative writing for assignments in departments other than Operations. Students did not share ownership for the texts they planned and composed individually, but they did help each other with the review process. Several teams shared resources electronically, organized members via email during the planning and developing stages, and used advanced features of the word processor (i.e. table of contents, embedded graphics, running heads, etc.) to produce professional looking documents.

Summary - All classes were held in the computer labs reserved for the course, enabling students to work with a consistent set of tools-word processor, spreadsheet, graphics, and web browser. By providing skills based training up front, and ensuring that expertise was available on each team, the teachers were able to require the use of the technology and focus on designing writing scenarios that were challenging and realistic. Students shared their knowledge and skills with different applications with their teammates for the benefit of the shared grade. The structure of the learning activities promoted the development of situation specific skills i.e. create a two column letter, or insert a graphic. Over the semester these situation specific skills were repeated and shared with teammates resulting in greater mastery and learning of the skill. By the end of the course the majority of students were comfortable with most aspects of the technology used in the course. Some students became expert with specific applications and others developed a core set of skills and competencies in all applications. More importantly, all students were able to use the technology to work together in collaboration to generate business correspondence.

Towards the Integration of Student Support Sytems Via the Internet

Peter J. Scott
Marion Phillips, Judith Fage, Katy Jennison, Roger Webb
The Open University
Milton Keynes, MK7 6AA, UK
Peter.Scott@open.ac.uk

Abstract: There is much more to a successful education system than the quality of the academic experience. How the educational environment supports a student is a key to that student's academic success and personal development. In this paper we discuss how we are attempting to move current stand-alone pc student guidance and support multimedia projects to the internet. In addition, we discuss how we are working on bringing our own projects together with other's work on database and information systems into a common and interdependent framework. For simple multimedia projects such as these, the move to the internet is both easy and compelling.

What guidance do students need?

Guidance and support for students is needed at every stage in a student's career: at entry; during study; between courses and at the end of a study programme. In an ideal educational environment the student should be seen as a whole person whose learning takes place in the context of past experiences, present circumstances and future hopes and aspirations. The UK Open University was founded on a multi-media approach combining initially print, television, radio and audio cassettes, face to face tuition and academic counselling, telephone communications and correspondance tuition to teach and support students. These 'traditional' media have been joined by video, and more recently by computer media such as CDROM, computer mediated conferencing, electronic mail, and now the Internet. We show that the move of simple forms of student support to the internet can be both compelling and straightforward.

Eg : UKOU Support Services for Students

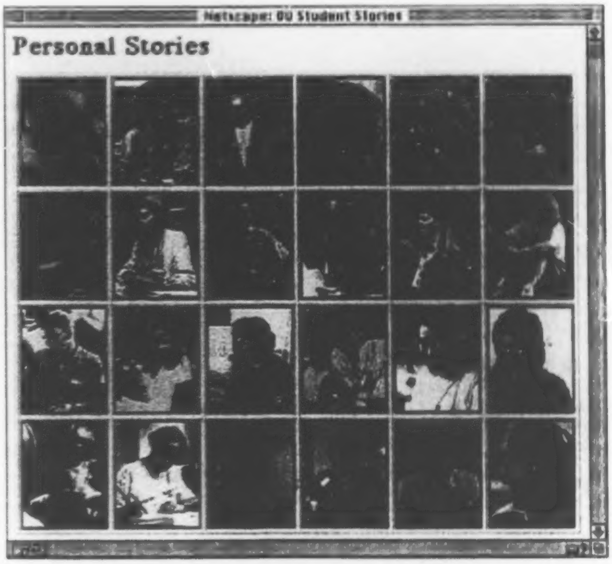

Figure: 5 An OU Support Services for Students Web page.

BEST COPY AVAILABLE

The Support Services for Students system was produced by the Regional Counsellors and Tutors and Academic Computer Services at the Open University using Macromedia's Director™. This system was converted to a html+RealAudio™ version very rapidly. The system aims to inform current and prospective students about the facilites offered by the UKOU and to provide a perspective on studying with the OU from a variety of different angles. The core of the system are stories told by OU students about how the issues affect them. In the figure [Fig. 1] from the experimental web version of the support services for students project - the student is invited to hear the personal stories of a number of UKOU students. Each story raises a number of issues which are then explored further within the system. Each individual screen consists of text and graphics with appropriate links to other pages - as in any hypertext, [Fig. 2].

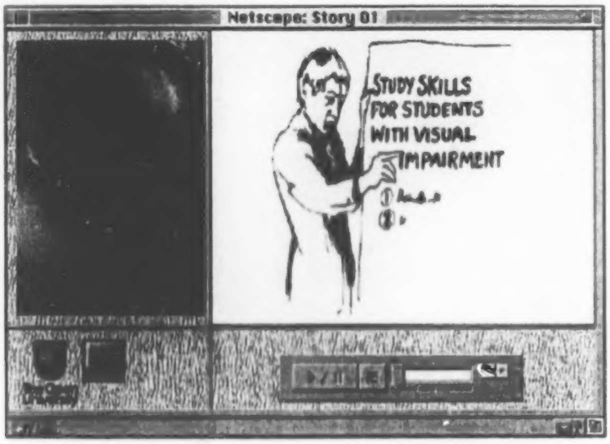

Figure 2: An SSfS Student Story with RealAudio.

Bringing CD Multimedia to the Internet to support students

There are many well aired issues in the contest between network delivered services and stand alone services.

Disadvantages

- The quality of the final product is invariably less - as one makes design compromises to suit students with slower connections. This is particularly true in an open learning context where adults are learning in their own homes, paying their own telephone/connection charges. It is still very difficult to deliver projects that require good quality video due to limitations in bandwidth and compression.

Advantages

- The project is instantly accessible from anywhere with network access. Anyone with a suitable pc and modem can now access these systems. They do not have to find out about the availability of the system and wait for the CD to come to them - as soon as they know about the system they can come to it!
- It is very easy log usage. Whilst one can count the number of CDs that are put in the post out to students but not the use that is made of them after they enter the postal system - and feedback is hard to collect from students - who have to go out of their way to return a questionnaire. However, every access to every page of the server of the web versions can be logged, and feedback is so easy for the student to give via email links on pages, that it is hard to stop users telling you what they think about the system, even before it is properly released! At the moment these systems are still experimental and we have no formal usage data - but we hope in due course to report on the network evaluation of the systems.
- Integration with other major network resources. From the students point-of-view the distinction between the distinct but related projects such as these two becomes significantly less. We are now working on integrating a number of complimentary systems into this simple framework.

Collaboration and Negotiation through the Learning Web

Mildred L. G. Shaw and Brian R. Gaines
University of Calgary, Calgary, Alberta, Canada T2N 1N4
{mildred, gaines}@cpsc.ucalgary.ca, http://ksi.cpsc.ucalgary.ca/SERN/, http://ksi.cpsc.ucalgary.ca/KSI/

Abstract: The *learning web* approach can be effective in supporting collaborative learning involving major groups of students operating as goal-directed, structured teams. It is natural for such teams to use hypermedia technology to record their own group processes in achieving their goals, particularly if communication with another team is an intrinsic part of their task. This article shows how an effective learning web can be established through a situation in which students play roles in customer and supplier teams concerned with a system development task. The only technologies used are commonly available web servers, browsers and text editors.

Summary

Learning web methodologies may be applied to existing courses in order to facilitate collaborative and self-directed learning and break out of the traditional lecture and classroom format (Norrie and Gaines, 1995; Gaines, Norrie and Shaw, 1996; Shaw and Gaines, 1996). CPSC451, a required software engineering course for Computer Science majors, is centered on projects that involve the students playing roles in teams representing customer and supplier organizations. Each student is assigned to two different groups of 10 to 12 students. In one group she is one of the supplier team, and in the other one of the customer team for a different project.

It has been natural to use the learning web in CPSC451 to support the group collaboration and the customer-supplier negotiations which in previous years were communicated only through documents. All the course materials are already made available to the students through the web, and it is a simple extension for students to place the documents relating to customer requirements, supplier comments and proposed solutions, the ensuing negotiations, and descriptions and screen dumps of the developed applications on the web. The notes below were given to students on how to use web facilities in a simple and natural way to manage their projects.

Using the Web for Requirements Tracking

The World Wide Web supports the sharing of structured multimedia documents with links to one another and to other material, not necessarily in HTML format. This makes it a suitable base technology on which to develop a requirements tracking system for software engineering that tracks the relationship between requirements, analysis, design, implementation, application and maintenance.

For CPSC451 we will use the web to develop a set of linked documents tracking the customer group requirements specification, the negotiation with the supplier group to clarify them, the design specification, the customer commentary on this, the implementation, acceptance procedures, and so on.

Rather than use special-purpose servers we will take advantage of the web's capability to link documents held in different locations, and generate a sequence of documents held in the directories of those in the customer and supplier groups. A single master index managed by someone in one of these groups will be used to make the distributed set of documents available to everyone in the groups.

Linking and Annotating Material

By putting all the customer and supplier documentation in the web directories of members of the customer and supplier teams it automatically becomes available to everyone. However, it is not linked together and it may not be obvious how the documents relate to one another. Two things can be done to improve the situation.

First, someone in the customer group should agree to become documentation manager for the entire project and maintain an index in their web directory of all the documentation from both customers and suppliers. This index will contain pointers to the distributed set of documents allowing them all to be accessed from one place. Anyone needing to look at the project documents will start with the index and click on a document in it to fetch that document. Anyone generating a new document that should be entered in the index should email its url to the documentation manager specifying where it belong in the index.

Second, while you cannot edit a document in someone else's account, you can fetch it with a web browser, save its source, annotate that source with your comments, and make the annotated document available in your account. Thus, the index will grow to be a sequence or a tree of documents such as a customer specification, a version annotated by the suppliers with queries about the specification, a version of this annotated by the customers with answers to queries, and so on. Similarly, an initial design specification from the suppliers can be annotated by customers.

Style of Annotation in HTML

You will need to establish some style guidelines for documents so that you can distinguish annotations from the original. One good technique is to use a horizontal rule before and after annotation. Tags for bold and italic can be used to mark particular sections of text to which you are making reference. There is no obvious or standard way of doing this. Experiment with HTML and decide on an approach for your group (but don't spend more time on an annotation scheme than you do on the actual software engineering project!).

What Should be Documented on the Web

Any documents that you can generate on paper you can also put up on the web, so that your project web should finally provide a complete account of all the activities of the project. For example, you can link to design material that includes screen-dumps as GIF images. In a real-world project that used the web itself to implement a client-server system you would even be able to link to the working system so that the requirements and design information was available for maintenance and enhancement support. If your implementation is on the departmental unix system then you should be able to provide a link that starts a live demonstration.

Conclusions

In the first paper on the learning web we argued that, given appropriate initial conditions, groups forming learning webs would organize themselves in a robust fashion to achieve their learning objectives. The experience with CPSC451 and other courses has shown this prediction to be correct. With the appropriate definition of the social dynamics, specification of the objectives, motivation of the participants and provision of supporting technology, the learning web approach is very effective in promoting collaborative learning.

The supporting technology is very simple and already widely available to educational institutions. CPSC451 used only standard web servers, browsers and text editors. No special-purpose tools were used. The students were third year computer scientists and hence had familiarity with computer use and text editors, but most had no prior experience in the use of the World Wide Web. We have found in other courses with students across a range of non-computing disciplines that the capability to prepare documents for the web is easily acquired in a few hours experience. The approach described in this paper can be used in any discipline.

The web created by CPSC451 students in 1996 is part of the learning environment supplied to CPSC451 students in 1997. Thus collaborative learning is being encouraged not only within cooperative groups, and across negotiating groups, but also longitudinally between classes in different years. The students who are learners in one year know that they are also teachers for the next, and hence can take pride in knowing that their achievements will be of value to others, not just exercises for the instructor to assess and then forget.

CPSC451 is an important course for students seeking employment in industry, since most potential employers see computer science students as lacking in the group collaborative skills that CPSC451 develops. The archiving of the materials on the web automatically creates a "portfolio" for each student through which they may show to a potential employer that they have had experience both in specifying requirements for others and in developing systems through teams that have negotiated requirements with others.

The Effect of Type of Courseware on the Achievement of College Students Enrolled in a College Algebra Course toward Problem Solving

Mark A. Shore, Math. Dept., Allegany College of Maryland, United States, marks@mail.ac.cc.md.us

Abstract: This study assessed the problem solving ability of College Algebra students using a variety of instructional software. A computer algebra system, a teacher written hypermedia program, a graphing calculator, and the combination of both the computer algebra system and the hypermedia program were used to teach and to solve distance and mixture problems. Post-test results showed significant differences between the groups. Students using the hypermedia program or the combination of both the hypermedia program and the computer algebra system scored significantly higher than the control group, the graphing calculator group, and the computer algebra system group on all problems and also the problems that tested for near transfer of problem solving skills.

Objectives

This presentation will show the differences in the effect between a hypermedia program, a computer algebra system, a graphing calculator, and the combination of a hypermedia program with a computer algebra system on college students' problem-solving ability in a College Algebra course. Further, this study will show if the type of courseware has an effect on near and far transfer of problem solving skills.

Perspectives

With the introduction of Computer Algebra Systems and Hypermedia Assisted Instruction, the choices for type of courseware are more diverse. [Palmiter, 1991] demonstrated that knowledge of calculus concepts for students using *Macsyma*, a computer algebra system, was significantly higher than for students taught using traditional instruction. Hypermedia programs can be designed to incorporate anchored instruction by allowing the user to navigate to different areas of the program to gather and use information. The amount of time required to teach the basic algebraic manipulations has reduced the attention teachers can allot to problem solving [Campione, Brown, & Connell, 1989]. As a result of the lack of time on problem solving skills, students are unable to develop the repertoire of strategies needed to solve word problems.

Sample

The sample consisted of five groups of students enrolled in College Algebra. All five groups had the same lecture time The control group, was not exposed to any computer instruction and only had the use of a scientific calculator. The second group was allowed the use of only a graphing calculator (*TI 85*). The third group was only permitted the use of a computer algebra system (*Derive*). The fourth group used hypermedia instruction, but was not allowed the use of *Derive* or the *TI 85*. The fifth group was allowed the use of hypermedia instruction and *Derive*.

Background

The *TI 85* calculator has a solver function built into the calculator that can solve linear and quadratic equations. *Derive* is a computer algebra system that will run on most personal computers (386 or higher). Because it is menu driven, *Derive* is easy to use. The purpose for *Derive* or the *TI 85* calculator in this experiment is solving the messy linear equations that are formulated from rate problems. *Mathquest* is a hypermedia program written by the researcher with the use of *Authorware*. The instruction of rate problems is anchored in two investigative games; one involving mixtures and the other involving distance and speed. *Mathquest* also has practice problems and tutorials on solving rate problems and incorporates sound, graphics and animation. *Mathquest* was designed within the context of anchored instruction.

Results

Since the ANOVA showed no significant difference in pre-test scores, a one-way ANOVA was used on the post-test scores. The results showed significant differences between some of the groups $F[4,75] = 6.076$, $p < .0005$. Upon further analysis, it was found that both of the groups that used hypermedia scored significantly higher than the groups that did not use hypermedia. The group that used hypermedia alone scored significantly higher than the control group (p value $< .1$), the *TI 85* group (p value $< .1$), and the *Derive* group (p value $< .1$). The group that used both hypermedia and *Derive* scored significantly higher than the control group (p value $< .005$), the *TI 85* group (p value $< .005$), and the *Derive* group (p value $< .005$). There were no significant differences between the control group, the *Derive* group, or the *TI 85* group.

Since the ANOVA showed no significant difference in pre-test scores for the near transfer problems, a one-way ANOVA was used on the post-test near transfer problems. The results showed significant differences between some of the groups $F[4,75] = 2.742$, $p < .05$. Upon further analysis, it was found that all four groups that used any type of courseware scored significantly higher than the control group (*TI 85* significantly higher than control, $p < .05$; *Derive* significantly higher than control, $p < .05$; Hypermedia significantly higher than control, $p < .1$; and the hypermedia and *Derive* group significantly higher than control, $p < .0005$). Also, the hypermedia and *Derive* group scored significantly higher than the *TI 85* group and the *Derive* group, $p < .05$. The ANOVA for post-test far transfer showed no significant differences between the groups.

Implications

The results show that the use of teacher generated hypermedia programs can cause significant increases in student ability toward problem solving. Anchored instruction may be the reason the hypermedia groups scored significantly higher than the other groups. In order for there to be a problem, someone must want to solve it. Without motivation for solving problems, students will not try as hard to solve problems. Using a graphing calculator or a computer algebra system allows students more time to set up more problems and become better problem solvers. However, a graphing calculator or a computer algebra system does not give the student motivation for wanting to solve the word problems. With hypermedia programs students have more of a motivation to solve the problems, because the problems can be anchored in a real life situation or game.

110Tech: Digitizing Humanities at Reed College

David L. Silverman
Classics and Humanities
Reed College, USA
dsilverm@reed.edu

Abstract: What can professors do better with computers than without them? Should faculty be encouraged to learn HTML authoring, and if so how? What characterizes the most valuable electronic course materials? How do e-mail lists best enhance a small class? How is data projection used most effectively for large lectures? The paper offers some answers through a look at the challenges involved with introducing an electronic component to a large freshman core course on antiquity taught simultaneously by twenty-two professors. It includes statistical analysis of student opinion polls conducted after a trial period; responses of students in technologically enhanced pilot groups are compared with the rest.

How do you take a freshman core Humanities course on ancient Greece, Rome, Judaism, and Christianity, team-taught by twenty-two different professors at the same time, a course taught more or less the same way for the last fifty years, and enhance it through the use of information technology? As recently as 1993, Reed College's Humanities 110 course, the only course in the entire college curriculum required of all matriculating students, had no technological component at all. Today it integrates electronic information in a number of different ways, and it provides a test case on helping faculty who have never taught with technology to do so.

At first we had some doubts about the wisdom of training the faculty members in the authoring of web pages. Although the learning curve was fairly steep, a consensus has emerged that this particular skill is worth mastering. It provides faculty with a powerful new tool for communicating information to students and putting them in touch with the resources which enable them to progress towards becoming independent researchers. We expect several different factors to push us further in the direction of training faculty to create web pages in the near future. First, the automated conversion of word processing documents will improve. Second, the prejudice of the scholarly community against electronic publication and in favor of print publication will decrease, giving faculty members more incentive to learn how to publish their work on the Internet.

The web pages created as a result of the 110Tech project are certainly not spectacular from a technological point of view, but they serve their purposes. One such purpose is simply archival. Before 110Tech, a limited archive was maintained for the course in the form of a shared folder on one of the campus servers. However, this folder contained only those documents which were generated by the secretary of the course: the syllabus and the paper topics. All of its documents were in a single format (Microsoft Word for Macintosh). Few students and faculty seemed even to be aware of its existence, and it was inaccessible to anyone not connected to the campus network, including students and faculty connected to the campus' computers by modem. Even PPP, which Reed began supporting in 1995, was of no help for this purpose as our PPP server does not support Apple Remote Access. The 110Tech project energized and extended an effort already under way to increase dramatically the number and range of course materials available in the archive by using web pages, and can claim this as a success. We now encourage members of the faculty to submit electronic copies of their handouts to the course's secretary, who converts them to HTML and links them to the course page. 110Tech faculty also pioneered the practice of posting complete texts of entire lectures on the course page, and this caught on nicely: five lecturers other than the 110Tech pilot members have posted entire lectures. Nor has there been any discernible decline in attendance at the lectures of those who do make complete texts available. This new archive takes advantage of the natural cross-platform quality of the web, making it a marked improvement over the old method, insofar as it is accessible to students who are not on the campus as well as to students who are using PC's or UNIX machines. See http://web.reed.edu/academic/departments/Humanities/Hum110/.

In addition to the course archive, the 110Tech faculty created a separate set of pages which focus on particular topics (e.g. the Afrocentric approach to ancient Greek history). These aim to introduce users to scholarly debates about central issues, and at the same time to point them to resources on the Internet for further research. Although these pages have no formal role in the course, they have been used to spark class

BEST COPY AVAILABLE

discussions and as the basis for papers. They are also the biggest draw for people visiting from off campus. For these pages see http://homer.reed.edu/.

A major limitation on what the project could hope to do emerged as we weighed it against the mission of the college. Like many another small private liberal arts college, Reed makes little pretense to being a resource for the community at large, beyond welcoming the public to its library, exhibits, certain lectures, and so forth. The educational resources of the college, especially the time and attention of the faculty, are intended primarily for the benefit of its own students. This makes sense at one level. In an increasingly competitive market for students' educational dollars, the personal attention of the faculty and the sense of a small community are ways to set such a college apart from the much less expensive state universities. The more we experimented with electronic distribution of course materials and class discussions in virtual space, the more it became apparent that the technology could permit us to offer the course to a wider audience, including students not enrolled at the college. But we encountered strongly negative reactions from the administration to any suggestions that the college might move in the direction of offering courses wholly or mostly conducted in virtual space. Hostility to the distance learning model was marked. As one technologically savvy senior member of the faculty put it, "We are not some kind of community college."

Humanities 110 is unusual, but not unique, in the way it uses faculty resources. The staff includes some people who have been teaching the course for twenty years and others who are teaching it for the first time. Those with less experience tend to follow the syllabus and other recommendations of the entire staff, such as for paper topics, very closely. At the other extreme, some of the veterans have long established techniques which work for them, and their version of the course freely deviates from the standard line. Because the structure is collegial, it is impossible to impose mandates about how the course is taught. Nor would that necessarily be desirable. The 110Tech faculty, confronted by our inability to legislate from above, has chosen instead to try to lead by example. Progress from this method is slow but sure. We built our web sites, packed them full of useful content related to the subject areas of the course, publicized their existence gently, and waited for our colleagues to say, "I should be doing this too." At this writing, five members of the staff in addition to the original five pilot conference leaders have voluntarily begun to learn HTML authoring and experiment with technologically enhanced conferences. The number should rise as a result our summer workshop for faculty, which will provide $500 mini-grants drawn from our Mellon funds as an incentive.

We conducted a short, anonymous multiple-choice survey of those students who came to the lecture on 1/31/97. The results (tabulated in the electronic version of this paper) were informative. The 110Tech students were significantly more likely to have accessed the Internet sites more frequently: 53.2% of them reported using the sites five or more times as against 31.2% of the regular conferences. However, a core of around 19% of students in both types of conference said they had never seen the pages at all outside of the classroom. This suggests that some better means of demystifying the process of getting to the electronic course components needs to be found for those students not comfortable using the technology. 110Tech students were slightly more likely than the rest to report finding the pages very useful (40.7% as against 33.1). Only a small percentage of students reported that they had seen the pages and found them not at all useful (4.6% overall). The students in the pilot conferences were also significantly more likely to have exchanged frequent e-mail with their instructors. 31.3% reported exchanging e-mail five or more times as against 23% of students in ordinary conferences. Fewer 110Tech students said that they had never exchanged e-mail with their instructors (25% as opposed to 34.8%). The latter figures remain surprisingly high for both groups. It suggests that the College could do more to publicize and promote the use of e-mail lists of the kind that permit a student easily to send a message simultaneously to her instructor and all of the other members of the conference.

The 110Tech faculty has also tried using data projection for the large lectures, with mixed results. Our early attempts at using data projection in the lectures were fairly clumsy. This came through in the survey. Although a majority of students said that the lectures were improved by the data projection (57.9% overall), an informal response to the survey by faculty in the weekly staff meeting had 7 of 8 respondents stating that the data projection detracted from the overall effectiveness of the lectures. A significant minority of students (9.3% of those in ordinary conferences) agreed. Most recently in the spring semester of 1997, more effective use of the data projection has been made. An informal consensus has emerged to the effect that what works best is to have the screen blank for most of the lecture, with a discrete block of time set aside for the projection of and commenting on digitized images. For text-based lectures which make no use of images, data projection appears to provide no significant advantages, and in some cases is merely a distraction.

Developing Multimedia for Educational Purposes

Alastair Smyth & Fergal McCaffery
Antrim Grammer School & University of Ulster
Co. Antrim, N.Ireland
email: northeast.lb@campus.bt.com & f.mccaffery@ulst.ac.uk

Abstract: The aim of this study was to explore the practicality of constructing effective educational multimedia courseware within the secondary school context. Many institutional constraints appear to militate against schools devising and constructing even comparatively modest multimedia resources, tailored to the needs of their own pupils and syllabi. Two quite different projects were undertaken: one, a comparatively modest interactive presentation to supplement academic tuition in two or three major curriculum areas; the other, an interactive instructional program required to teach concepts as preparation for practical classwork. A *Why?—What?—How?* requirements scenario was employed to advise and guide the young designers. Both project teams succeeded in creating a logical and coherent structure, incorporating non-sequential as well as linear navigation possibilities. The systems were designed through the use of iterative prototyping and then the usability of each system was assessed before proceeding to full development and implementation. With everyone's sights constantly set on the target end users, it was a surprise to discover that those who learned most were, in fact, the younger members of the project teams: of necessity, theirs had been a thoroughly effective and detailed engagement. There were other advantages too: the approach encouraged flexibility of teaching methods: broad-ranging, non-traditional, cross-curricular collaboration and resource sharing; and 'in-house' easily accessible target user population imparted a strength to the design of the system. As a result of this project there was general consensus that we had just begun to glimpse the potential of multimedia technology for developing new study skills (while reinforcing existing skills), in a pupil-enticing environment.

Introduction

Given that previous research has shown that effective multimedia assists learning, the original problem was : would an interactive digital storage program delivering text, still and moving images, and sound (ie. multimedia technology) be a realistic proposition for development by teenagers in schools?

CBL literature widely assumes construction of learner-centred instructional multimedia courseware but nowhere appears to address the present impracticality of such activity in the secondary school context. It is no solution simply to place such technology as multimedia at the disposal of any subject teacher wishing to develop courseware: good hardware/software is too expensive for exclusive departmental use, and multimedia merges disciplines which, historically, have developed in some isolation.

Requirements Analysis

Initially questionnaires were issued to the staff to try to uncover the technology being used within schools and and it was discovered that a range of commercial multimedia was in occasional use, for revising or supplementing classroom tuition. However teachers disliked the fact that the material was often too wide and general for their purposes, but favoured the good technical quality and convenient integration in one place of a variety of media resources.

Two curriculum areas were identified, one combining a wide variety of media resources to supplement traditional classroom teaching, the other delivering conceptual and technical training in preparation for subsequent practical work in the classroom. The former (geography) was keen on centralising resource materials for a local study concerning the Giant's Causeway in County Antrim, Northern Ireland. The second project proposal arose from a pedagogical need within the Media Education department:

Initial design

From the functionality requirements analysis, a description was devised of actions required from users and, from the task analysis, how the user would perform an action to accomplish a task. Tests were then written for each instructional objective with practice interactions then devised for each test item. Nextly usability testing with the target users identified an acceptable level of performance and iterative testing of prototype samples helped to identify whether the design suceeds in fulfilling the requirements.

Prototyping

Limited but practical working models for each project were produced and tested. Observation of a representative, small number of users was conducted to validate client/user-expectations and to assess how far users would understand content and operation. The extent of iteration was determined by user acceptability. The Causeway prototype tested the main menu, preliminary screens for each topic and their full selection of visual and aural transition effects and media component types. The software - 'Astound' - allowed information to be directly entered on the screen slide: automatic programming of the computer was achieved by the software writing corresponding lines of computer code. However, the Video project team had some scripting experience in HyperCard and were able to implement a greater degree of interactivity and computer dialogue to motivate user engagement. User-attitudinal considerations dictated that system dialogue should always be made relevant, clear and concise, and that any error messages should be supportive and non-challenging.

Implementation tools

Pupils involved in the Causeway project had no previous experience of working with multimedia software. Gold Disk's 'Astound' software provided an easy-to-use tool, appropriate for constructing the type of presentation required by both client and users. The main window allowed pupils to create, edit and preview each slide by accessing convenient menus, tools and icons. The Video project required some variety of input by users governed the choice of HyperCard software. Its HyperTalk programming language (userlevel 5) is very accessible to secondary school pupils and use is not dependent on experience or aptitude for programming.

Reflection & Evaluation

Building multimedia courseware within the secondary school environment can result in much more than the creation of an artefact. The general aim of the projects represented in this study was to devise and construct a computerised system offering dynamic representation: textual, auditory and visual learning. The majority of the electronic media materials were custom generated by the pupils forming the project teams. These young people experienced a sense of personal responsibility for the success of a wide variety of educational activities: research (print/visual/audio texts); drafting/evaluating/redrafting in a variety of media; collaborating in groups of varying sizes, across curriculum subjects; purposeful discussion; using a variety of technologies; producing programs for specific user audiences. As well as the courseware being largely successful in achieving the set goals, the primary benefits of such work are for those producing the material.

The importance of the teacher as a subject and method expert can be significantly reduced by CBT. However, developing educational multimedia as above poses little risk to teachers becoming little more than 'general facilitators.' The burden of repetitive lecturing is lifted. Interpersonal skills become more significant, allowing teachers to develop better and more individual relationships with pupils. Understanding the learning process as well as the new technology becomes important. Careful management, with the full commitment and enthusiasm of teaching staff, greatly facilitated non-traditional and cross-curricular innovatory teaching methods during the current study.

Future development

For schools, the implications of such new technological communication as interactive and instructional multimedia are great. The secondary school curriculum contains a great diversity of topics for self-access interactive learning material targeted to the needs of specific learners. Producers of such material should experience and enjoy the development of new study skills and reinforcement of existing skills in new contexts. The projects involved in the present study necessarily employed only low-end multimedia tools. As a starting point, such software enables novice pupils to construct programs quite quickly and with some comparative success. From such experience, it is planned that they will progress to more complex projects employing more sophisticated, high-end multimedia software, such as Macromedia Director or Asymetrix Toolbook.

Inter and Intra Courseware Structure for the Inter-operability of CAI Programs

J.S. Song (Korean Educational Development Institue. Seoul, Korea)
S.M. Jung (Korean Educational Development Institue, Seoul, Korea)
H.Y. Yoo (School Of I.C. Ajou University, Suwon, Korea, e-mail : hyyoo@madang.ajou.ac.kr)
G.H. Jung (School Of E.E. Ajou University, Suwon, Korea, e-mail : khchung@madang.ajou.ac.kr)
J.T.Lee (School Of I.C. Ajou University, Suwon, Korea, e-mail : jtlee@madang.ajou.ac.kr)
K.H. Choi (School Of I.C. Ajou University, Suwon, Korea, e-mail : khchoi@madang.ajou.ac.kr)

Abstract : Most of CAI programs are developed by authoring tools are not inter-operable and the non inter-operability hurts the diversity of course works and reduces students' desire on knowledge. To resolve this problem, this paper proposes a way to develop CAI programs through Inter courseware structure and Intra courseware structure. Intra structure is a structure that allows to develop an independent CAI program with combinations of various educational multimedia objects. Inter structure produces a synergistic effect that can not be expected in a single CAI program, by allowing the inter-operations among the pre-made CAI programs.

I. CAI Programs Based on Intra and Inter Courseware Structure

We model a CAI program as a software that is constructed with three appropriately combined elements. The elements are teacher element, student element, and content element. The teacher element implies how to teach students with what kind of contents, such as the aim and the content of course work, teaching strategy, and feedback strategy. The student element is the behavior type of student, the level of student, and the interactions between students and CAI programs. The content element is various educational multimedia objects used for explaining the content of course works efficiently.

For example, consider a CAI program that, to teach an add operation with two one-digit integer numbers, after representing each number as an apple, asks students the result as a number and then, shows the feedback. In this case, numbers from 0 to 9, apples, sound or graphics for correct answers are considered as the educational multimedia objects. Inputting correct answers with keyboard and the level of student are the student elements. To try to make the student understand add operation by showing graphics for add processes is a teacher element. Depending on how these three elements are combined, various CAI programs can be generated.

The Intra courseware is an infra structure that allows to build CAI programs by interconnecting dynamically the above three elements stored in the database. Since it is possible to reallocate dynamically the internal resources such as data and program code demanded by users while operating the coursewares developed following this structure, they can implement more functions than in the traditional CAI programs and allows to re-use the resources for other CAI programs. For an instance, all resources such as numbers, apples, graphics and sound used in the above add operation CAI program can be re-used for other CAI programs.

It is not recommendable to make new CAI programs for every coursework, though it is easy to edit various CAI programs re-utilizing resources with the help of intra courseware structure. It is possible to produce a new educational effect by using a part of the functions contained in pre-made CAI programs. Especially, it is very hard to analyze the possible behaviors of students in advance and apply them to editing CAI programs. Instead, by co-operating independent CAI programs, a synergistic effect may be obtained. For this purpose, this paper proposes "Inter courseware structure". The inter courseware is an inter-operation and inter-communication model between the coursewares developed for different purposes. In the Inter courseware structure, the possibility to share resources among CAI programs and to re-use CAI programs increases.

II. Implementation issue and future work

We have implemented SAEBIT to realize the Intra courseware concept [Jung and et al 1995]. SAEBIT supports the functions associated with constructing new CAI program units combining frames or OEM (Operable Educational Multimedia) with the pre-mentioned three elements. The frames are stored and managed in the

BEST COPY AVAILABLE

OEMDB (Operable Educational Multimedia Data Base). New OEM objects are made with the combinations of three elements. It is possible to realize a new CAI program by re-ordering the pre-constructed OEM objects. To make combining the OEM objects easier, "Logic objects" are introduced.

Figure 1 shows three examples of constructing CAI programs by SAEBIT. They utilize five same OEM objects. But the constructing strategies they hire are "Programmed Control", "Loop", and "Learner Control", respectively. The OEM objects in figure 1 are represented as five icon's : *start, ending, content, feedback1, and fedback2* while seven icon's, *branch, cond1, cond2, loop, interact, select1, select2* are logic objects. Figure 1.1 shows that the five OEM objects are interconnected with each other by logic object branch that decides the next displaying frame according to students' input. In figure 1.2, the five OEM objects are interconnected with each other by a logic object, loop for a repeated lesson. In figure 1.3, based on the learner control strategy, the five OEM objects are interconnected by three logic objects : interact, select1, and select2.

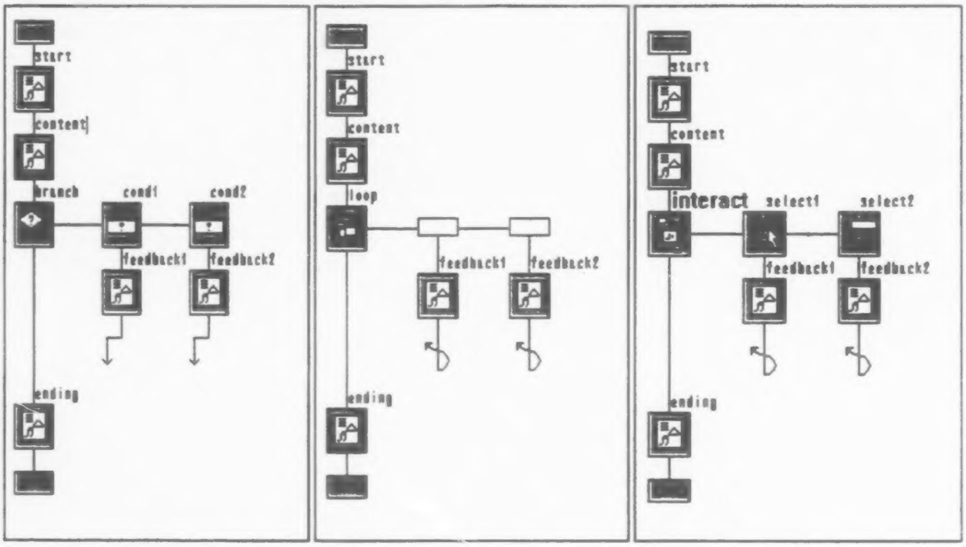

Figure 1.1 Programmed Control   Figure 1.2 Loop   Figure 1.3 Learner Control

Figure 1 : Examples of Inter courseware implemented by SAEBIT

For a CAI program to have an independent function and to co-operate with other CAI programs successfully, it requires a communication structure to interconnect CAI programs, and an appropriate communication handling process. With the communication capability, the CAI program can support the demands from students who are using other CAI programs. The way that some functions of a CAI program can be provided to other CAI programs is similar to using URL in Internet to navigate Hypertext, in terms of the functionalities. But in terms of the access unit, it requires a finer granularity than Internet does. This implies that when a CAI program tries to use a function supported by other CAI program during its execution, it is desirable to execute the requested CAI program partially rather than execute the whole program.

This paper proposes a way for a CAI program to handle the messages requested by other programs to allow co-operations among the programs. The messages are handled by a special sequencer and the handling routine is similar to that for the reactions during execution of learning process. It is close to a dynamic DFD (Data Flow Diagram) that several CAI programs are being inter-operated.

It is expected to improve significantly the utilization of CAI programs made by teachers, once the Inter courseware function (currently being upgraded) is added.

Issues in The Development of Computer User Interfaces for Disadvantaged Multicultural Communities

A.Stander
School of Business Informatics
Cape Technikon, P.O. Box 652, Cape Town 8000, South Africa
adrie@commerce.ctech.ac.za

Abstract: The design of computer user interfaces for disadvantaged multicultural groups presents a challenge to interface designers. This paper examines some of the key psychological aspects such as social class, locus of control, role of the sexes, age and language that could possibly influence the human-computer encounter of such groups. The results of a study done on two groups of students from multicultural backgrounds to determine differences due to cultural factors when using simple text based interfaces in simulated and real-life situations are discussed.

Recent political change in South Africa has caused major changes in the educational structure. Not only was the entry of previously disadvantaged groups into the higher levels of education greatly increased, but the process of affirmative action placed many previously disadvantaged workers in positions where they need to use computers. As a high percentage of these students has never been exposed to technology or even electricity, working with a relatively sophisticated instrument like a computer involves a major paradigm shift for the student. The multicultural nature of the South African population, low literacy levels [Hartshorne 1996] and extreme poles of social development pose a unique challenge to interface design. This paper discusses some of the cultural issues that could influence the human-computer encounter in a disadvantaged multicultural community. The results of ongoing research to determine cultural differences when using computer user interfaces in simulated and real-world environments are also discussed.

Various cultural aspects could possibly influence the effectiveness of the user interface in a multicultural society. Language is an important factor and studies have shown that simple translation will increase productivity [Bodley 1993]. All eleven official languages do not however contain the necessary technical vocabulary. Mothers from a lower social class typically use a limited language code when communicating with their children [Mussen et al. 1984]. As this cause the children to think in more concrete and less conceptual terms it may influence the human computer interaction, particularly where a high degree of abstraction, like in graphical interfaces, is used.

Symbolism is problematic as symbols like light bulbs, recycle bins and VCR controls do not feature in the life of students living in slum and backward rural conditions. Lack of exposure to technology might negatively influence user attitude [Downton 1991] with a corresponding inhibition of learning and performance. An external locus of control is common among disadvantaged groups due to the high degree of rejection, hostile control and criticism they experience. As the sense of being out of control is largely associated with the inclination to avoid stressful situations, the hostile South African political environment of the past may therefore lead to a situation where students from these groups might prefer to avoid situations where they do not feel in control. The strong differentiation between the roles of the sexes in the indigenous cultures can also influence the encounter with the computer [Downton 1991] as it has been shown that the different orientations towards problem solving can have an important influence on computer usage. The intracultural factors of social class play a significant role in determining how a person acts and thinks [Baruth & Manning 1991]. Such differences may sometimes be more pronounced than those resulting from cultural diversity and may influence the orientation of the user towards abstraction and generalizations. As each lifespan stage has its own unique developmental characteristics, age as an intracultural factor was found to be a powerful predictor of a user's ability to learn complex computer systems [Egan 1988] and it is therefore important to take the age group of expected users into account when designing user interfaces.

Race, being based on the anthropological concept used to classify people according to physical characteristics such as skin and eye colour, provides no culturally relevant information, and can consequently not be considered as an influencing factor.

Due to the subjective nature of cultural factors, complex test instruments are needed to determine the influence of each factor and even if a factor is found to be an important one, the finding does not necessarily apply to all users of a particular system. Few, if any, studies address the problem of interface design for a wide cultural mix. Existing guidelines mostly assume a specific cultural group as the target and base the design upon this assumption.

As it is important for all users to be able to use simple interfaces like those used for automated banking, the first step was to determine if any significant differences exist between cultural groups when using a simple text based interface. Using a simulated interface on a microcomputer network, the time to complete a simple questionnaire in English, was measured for a sample of 277 Cape Technikon students representing eight cultural groups and six languages. The students selected have all been exposed to computers for six months and were at a similar academic level. No significant intercultural differences were found.

In a real life study 2750 students were tested during the annual registration of students at the University of Stellenbosch. Medical, engineering and commercial students were tested for the time they took to complete the interactive registration process. All students were in their second or higher academic year. As in the simulated process, no significant intercultural differences were found, despite the more complex nature of the registration system.

The lack of intercultural difference is not surprising as all students were at equivalent literacy and training levels and did not have to interpret any symbols in terms of their cultural background. This does however point out that text based interfaces does not cause serious intercultural differences in the human-computer encounter. At the time of testing, the technology to test graphic interfaces was not available, but future tests on this type of interface is expected to show much more cultural differentiation. As symbols may be a way of overcoming low levels of literacy, where even people who cannot read can recognize a graphical image, future research will be aimed at the determination of problem areas in symbol based interfaces when used by multicultural communities with low literacy levels and little previous exposure to computers.

SITUATED LEARNING: APPLICATION TO EDUCATIONAL TECHNOLOGY

Denise Stockley, Faculty of Education, Simon Fraser University, Canada, dstockle@sfu.ca

Wolff-Michael Roth, Faculty of Education, University of Victoria, Canada, mroth@uvic.ca

Abstract: Situated learning theory contributes to a growing body of research in the human sciences that explores the way learning derives from participating in social worlds. This theory has found a wide-spread audience through the book entitled, Situated Learning: Legitimate Peripheral Participation (Lave & Wenger, 1991). Lave and Wenger raise key questions about the nature of social settings that supported or inhibited the learning of authentic practices by newcomers. Although Lave and Wenger had warned that situated learning is an analytical perspective, many researchers attempt to use its central notion in a prescriptive way to create better learning environments. The purpose of this paper is to establish how such a relation between the theoretical framework and the application in the field of educational technology can be established. This paper therefore presents: (a) a brief overview of situated learning theory, (b) the implications of the theory for learning and learning environments, and (c) issues arising from the application of situated learning theory to educational technology.

Learning in an online environment provides opportunities for learning to occur within situated learning contexts that are based on authentic tasks (i.e., when programs like Hypermedia and Virtual Reality microworlds are being used, Harley, 1993). These programs can provide contexts of many different types including: (a) the actual work setting, (b) a highly realistic or 'virtual' substitute of the work setting, or (c) in an anchoring context such as a video of the multimedia program (McLellan, 1994). These settings may promote communities of practice as learners engage and interact with the program and with other members of the community. Further these programs provide opportunities for participants to engage in the four strategies suggested by Brown, Collins and Duguid (1989) to promote co-participation in an apprenticeship model. In that within these types of programs participants can engage in collective problem solving, display multiple roles, confront ineffective strategies and provide opportunities to develop collaborative work skills in both an asynchronous and synchronous context.

More often than not, however, non-authentic tasks are frequently embodied in educational technologies. For example, computer simulations that are designed to show flashy pictures, film strips, and other seductive details are less likely to engage the student in active learning, in comparison to other simulations that require problems to be framed and resolved. The former simulations (e.g. eye candy types) do not promote situatedness; thus reducing users to sightseeing tourists, rather than active travelers who make an attempt to try to understand the culture and people of the countries they are visiting (Damarin, 1993).

Students in non-authentic simulations can then be thought of as consumers of knowledge. However, they are shoppers who are knowledge building as they are unaware of what constitutes good value for their learning experience or good quality for their online learning activities. Ruhleder (1995) agrees with this concern, in that information that is presented in an electronic format may be given undeserved authority because of the 'scientific' objectivity associated with technology. Damarin (1993) further suggests that although it may be possible to design hypertext programs that would encourage students to use the languages, the norms and to share the local histories within that context it is highly unlikely. She argues that based on the current direction of educational hypertext development, the use of the principles of situated learning theory is not assured in educational technology contexts.

To provide another example, to date there exists much "educational" media that engages students in practices that are neither authentic nor do they lead to authentic practices. If for example, a chemistry-related activity asks students to shoot chemical formula from the sky as quickly as they can, these students are not engaged in the activities and practices that characterize chemistry. Rather, they learn to react quickly, and at best, to memorize the formulas required by the game. These programs, although entertaining, provide little if any authentic learning experiences for the student and are not transferable outside of the simulation in which it has occurred.

The technology then really needs to be developed using an authentic learning perspective, multimedia based tools can further promote situated learning as learners with diverse knowledge and perspectives are supported. This quality is important in today's classroom environment as teachers are constantly being encouraged to view students as individuals with individual learning styles. A concern that Damarin (1994) brings forth though, is the social and economical situatedness of what sparks the development of a tool and it's later use. These at times, political situations result in the establishment, continuation, modification or demise of various technological tools. This argument suggests the role the larger community of practice plays in the design and implementation of technological tools.

As a result, the principles of situated learning have considerable implications for how educational technology tools have to be designed for authentic learning to occur -- as situated learning has provided the framework of viewing the community of practice as the center of the technological environment (Damarin, 1993; Harley, 1993). As such, technological tools cannot be thought of as separate from the human interaction, as both are integral components of this community of practice. It is then critical that artifacts not be isolated rather that they are woven into the context in which they are to be used in (Brown & Duguid, 1993).

Educational technology needs to promote learners that are actively involved in their learning experience and needs to acknowledge that knowledge is being co-produced by the learner and the context in which it is occurring (Damarin, 1993). Therefore, designers of technological tools need to provide the tools that are required by the learner and as opposed to providing bells and whistles that may never be used by the learner. By following this design method learners are part of the design process and thus moving away from the traditional design model of guessing what the learner will require ahead of time and building the tool (Brown & Duguid, 1993).

Educational technologists need to further design tools in a manner that is commensurable within a situated learning theory. These tools then need to be made available to newcomers to allow for an increased participation into the practices of the community into which the learner is to enter (Brown & Duguid, 1992). That is, this technology needs to be flexible enough to allow newcomers to engage in authentic practices but at the same time allow this participation to increase over time until newcomers are old-timers themselves. That is, educational technology needs to allow for newcomers to engage in a trajectory of legitimate peripheral participation which increases in unison with their increasing competencies in the target practice. This ensures the legitimacy of the technological tool to be introduced into that particular community of learners.

Apprenticeship models can also be supported within the field of educational technology through use of tools such as conferencing systems and e-mail. A good example is the way in which students participate in a collaborative assignment for an online course. Initially, an old-timer would explain or demonstrate the technical aspects of the tool to be used to the newcomers, thus promoting a community of practice. These students would then develop their ideas through sending messages back and forth to determine the focus of the particular assignment (e.g., through use of a conferencing tool such as V-Groups in the Virtual University). Once the focus was determined, students would continue collaboration through the medium until the assignment was completed. Thus, both the old-timer and newcomer are active participants in the community of practice.

This ability to participate in a community of practice asynchronously is critical to the success of the online courses that are currently being offered at university campuses worldwide; as students who are not able to make it to campus are now able to feel that they belong to a larger community, something that the traditional model of distance education (the correspondence model) does not allow for. As education is moving towards a model that incorporates technologies it is critical that situated learning theory is taken into account in order to ensure that authentic learning experiences occur. This use of technology further ensures that connections are developed and maintained between the learners and their community of practice (Brown & Duguid, 1993).

Abstract: This investigation documents how collaborative processes of knowledge construction over time and space are structured and organized utilizing two-way video conferencing strategies for distance education in an undergraduate course in child development at two universities. The impact of a learning-centered approach to video conferencing, the on-going technical and organizational support needed to sustain changes in pedagogy using new technologies, and the mediating force of television frameworks are discussed.

This study examines a year-long collaboration among organizers from two universities who designed and implemented two-way video conferencing and email activities as an integral part of a child development practicum. Each quarter the two classes met four times for video conferences that lasted one-hour and twenty minutes. In addition to following the same syllabus, all students at both campuses conducted fieldwork with children in a unique after-school program centered around computer-mediated learning known as The Fifth Dimension. The practicum encouraged university students to combine theory and practice. The distance learning (DL) element of the course was envisioned as a medium through which students would share their empirical/theoretical syntheses in a collaborative learning environment. Students were expected to be active participants during the video conferences and lectures by professors were kept to a minimum. This scenario is unlike the usual DL environment where one professor, teaching from a host school, instructs students at his/her site as well as students at a distant site. In this more common arrangement, models of traditional classroom teaching are imported wholesale into the videoconferencing setting; i.e., the DL course is conducted by one instructor who lectures to a relatively passive audience of local and distant students. The project discussed here was carried out by two professors every quarter who collaborated with one another and with a research assistant whose job it was to plan the video conferences and provide the support necessary to carry them out. While much of the literature on DL emphasizes the supposed need to imitate as closely as possible the "normal" classroom setting, the goal here was to implement a use for the technology that went beyond the average university lecture. The child development practicum was organized to move beyond the traditional dichotomy of teacher-centered vs. student-centered to a more productive use of instructional technology that was *learning-centered* [see Lave & Wenger 1991] -- - an approach which reflects the complexities of strategically organizing interaction so that responsibilities for participation continually shift among participants.

The research questions explored here include 1) What elements of the instructional approach to DL contributed to students' active knowledge construction? and 2) How was collaboration facilitated and/or constrained between the two universities? To investigate these issues, participant observation fieldnotes by undergraduate students, support personnel, and instructors were gathered. E-mail correspondence among students and program implementors were collected for the duration of the project. In addition, social interactions were documented between and among participants utilizing two data sources: video tapes of the DL classes and a Web page that provided a bulletin board and chat room options. Semi-structured interviews of undergraduate and elementary students were gathered to verify attitudes and assessments found in participant observation fieldnotes. Interpretations of data were informed by socioculutral theories. In these paradigms the assumption is that knowledge production cannot be studied independent of the social context and that cognitive skills are considered to be promoted through joint activity (proximal and distal), see [Cole & Cole 1989], [Stone 1996], and [Vygotsky 1978].

The main findings of the research included the following:

BEST COPY AVAILABLE

* Particpation in DL classes with a group of students who were attempting the same kind of fieldwork and struggling with the same theoretical materials created a broad sense of shared purpose for the undergraduates and positivley influenced their attitudes toward the coursework.
* The role of the professors was to moderate the conference and to follow-up on presentations made by students. Their participation was evaluated positively when they briefly elaborated on or re-directed students' understandings of the key theoretical concepts, and was evaluated negatively when they resorted to lecturing for more than ten minutes. Students were the least tolerant of lengthy lectures delivered by the distant professor. Many students even assigned malevolent intentions to the professor from the distant campus, writing that he or she was trying to "show off" or "take over".
* The undergraduates who were either called on or who volunteered to share theoretical interpretations of their data gave the most positive evaluations of the video conferences and reported being proud of their demonstrated abilities to interpret the readings and effectively apply the relevant concepts. Non-presenting students wrote that they were able to develop more sophisticated understandings of the theories after hearing the examples outlined by their peers and by participating in the resulting discussions.
* The students reported in DL fieldnotes that the possibility of having to present their ideas on "television" to an audience of distant peers led them to carry out their assignments with a great deal more effort than they ordinarily would have invested.
* The television framework for social interaction did not always lead to a collaborative learning environment. Students reported that since speaking was such an "event" in the context of videoconferencing (i.e. the camera operators, audio technicians, moderators and distant audience members all had to gear up for participants) the they did not feel comfortable making brief supportive remarks such as "I agree" or "That was interesting".
* The distance made it possible for students to be less considerate of their peers at the other campus and they had a tendency to be more judgmental about their ideas and comments. However, these dynamics were discussed in the regular classroom settings and the students at both campuses reflected openly about these tendencies and often tried to make up for misunderstandings by writing supportive email and by thanking participants during the video conferences.
* The success of this videoconferencing endeavor was due in large part to a research assistant, whose job it was to plan the video conference by delineating the structure of who talked when and by providing support in terms of the technical aspects of video production[1]. In order to coordinate between the two university sites, the research assistant attempted to stay in continual contact with the course instructors so that an adequate degree of shared meaning about the collective process of on-line collaboration could be maintained. Her supportive role was critical to the effective implementation of videoconferencing given the continual change in site instructors and their multiple realities.

Despite the discontinuities brought into the activity by multiple faculty participants and the sometimes inhibiting framework of television, collaboration in this setting was successful in terms of overall program goals: active on-line engagement and co-production of knowledge. Promoted here is the view that learning-centered collaboration across distance can be a powerfully validating force for undergraduates struggling with the challenges of ethnographic fieldwork and theoretical applications.

Abstract: This study explored computer-mediated learning in an after-school club, in which elementary-aged children worked with undergraduates from a local university. Collaborative participation by undergraduates was characterized as requests for explanations, information, suggestions for off-line tool use, and displays of encouragement. Computer software designed for single-users was shown to constrain collaborative talk-in-activities and the co-production of mathematical knowledge.

This is a preliminary investigation into the collaborative construction and communication of mathematical knowledge during computer-mediated learning activities so that we may better determine design requirements of software. In particular, this study focused on opportunities for undergraduate students to collaborate with elementary-aged children on commercially available computer games in an after-school club. Social interactions during collaborative learning events involving computers potentially stimulate mathematical knowledge construction. This study examines the routine practices used to accomplish computer games and how this mediational tool both constrains and encourages children's development of mathematical knowledge. The research findings in this study examine mathematical problem-solving discourse involving computer games to expand our understandings of the processes of collaboration in computer-mediated learning and our understandings of the interaction between software and activities designed to be collaborative.

Sociocultural views of learning and development, the theoretical framework for this research, hold that cognition is "socially constructed", "socially distributed", and "socially organized", see [Crook 1994] [Ochs 1988] [Stone 1996a] [Vygotsky 1978]. From this perspective, it is assumed that knowledge production cannot be studied independently of the social context. Further, cognitive skills are considered to be promoted through joint activity in which semiotics (tools and signs) mediate development during social interaction.

Our research was guided by the following research questions: 1. What is the nature of collaboration during computer-mediated learning involving mathematics. 2.How does mathematical game software influence the collaborative production of mathematical knowledge?

To document the social processes of collaborative learning and computers, qualitative methodologies were used in this study. The data in this study are taken from a larger investigation into the development of mathematical and scientific literacy in an after-school club. The after-school club is located in an urban school district with a predominately Latino student population in the southwestern area of the United States. In this club, children worked with undergraduates from a local university who were enrolled in a child development practicum that required them to participate in the club twice a week for nine weeks. The goal of undergraduate participation was to connect theory to practice by reflecting on and using social theories of human development as they worked as tutors. The corpus of data consisted of 10 videotaped sessions of approximately one hour in duration.

To illustrate the significance of pairing undergraduates with elementary-aged children, this study focuses on Puzzle Tanks, a computer game designed for one player and consists of four levels of difficulty [O'Brien 1985]. The goal of the game is to measure out a specific volume of liquid by filling and emptying tanks, as well as transferring liquid from one tank to another. The lowest level of difficulty, *Beginner* level, uses two tanks and one storage container. At this level, problems are generated according to a formula that determines the desired amount of liquid to be transferred into the storage container. This formula is $x = m \cdot a + n \cdot b$, where x is the desired volume, constants $m,n \in Z$, and $a,b \in N$ are the tank capacities. Because any values chosen for m, n, a, b will result in a value for x, all problems in the beginning levels have a solution. Higher levels of the game generate random integers, resulting in the possibility of no solution. Specifically, children are expected to create a solution to a relatively novel situation by utilizing some sequential combination of addition, multiplication, or subtraction procedures to determine the produce value.

The main findings in this research included the following:

- Undergraduates, in the role of a tutor: a) socialized children's attention to important aspects of mathematics activities on computers (e.g.,critical information found on the screen by encouraging children to read directions when initiating a game or when problems of understanding arose; b) encouraged off-line tool use by suggesting that students use paper and pencils to figure out difficult problems; c) contributed to children's opportunities to communicate about their mathematical knowledge by asking for explanations and justifications (consistently found in this data set) and, d) contributed to the joint construction of motivation for continued play through questions and responses to students' actions also created opportunities for the co-display of interest in the game and solution strategies. As a consequence, motivation for continuing a game was not solely an individual construction but a result of the social organization of the collaboration.
- Although the computer games in this study were purposely framed as collaborative activities through the use of adventure guides, i.e., directions for how to play the game embedded in a fictional narrative, it was still very common for children to begin a game by randomly clicking the mouse on various areas of the screen in an attempt to determine specific game procedures. The pattern of random exploration was found to be consistent across computer games; there is an interaction between the affordances of software and how collaborative mathematical activities unfold.
- The design of PT software technology fits into the general single-user paradigm typified in current commercial software; as such this software will *permit* social interaction but it is not designed to encourage it, in fact, it is oblivious to social interactional processes. Consequently, this form of software constrained activities organized to promote the co-production of mathematical knowledge. The common pattern of students focusing on the screen persisted even when undergraduates offered suggestions that required either a response or off-line involvement.

In conclusion, the collaborative activities with undergraduates evidenced varying degrees of participation by children. For example, it was common for undergraduates to assist children in focusing on important aspects of computer-games, e.g. screen displays. This form of assistance, however, appears to be successful only when students were experiencing troubles with the game. When problems were not sufficiently difficult to stop play, children would continue to use the mouse, paying little attention to the information on the screen. Undergraduate participation also encouraged the use of off-line tools such as paper and pencils to represent of problems. However, the computer game's similarity to video games, i.e., a single-user approach, made it easy for children to continue using the mouse and ignore any suggestions offered by the undergraduates. In other words, the software design encouraged individual involvement rather than collaboration. Collaborative talk-in-work, then, was not an intended by-product of the software design but rather a product of ongoing problems with understanding or game procedures.

While many of the strategies for collaboration used by the undergraduates did not necessarily lead to the co-production of mathematical talk or reasoning, that was not the case for explicit requests for explanations. When undergraduates asked children what they did to accomplish the task, these question frequently resulted in children producing explanations. Nonetheless, these explanations tended to be brief or provided no evidence of a deep understanding of mathematics.

The significant issue is the interaction between expectations for collaboration and the constraints placed on both knowledge production and collaboration by the software. For example in PT, there is no way to manipulate problems to investigate patterns of similarity and differences. As a consequence, it would be difficult for Ivan to explain why any one problem was impossible outside of stating that no combinations worked. Had the "presented problem" been directed toward finding a pattern, PT may be a much more valuable tool insights into mathematical principles. It is crucial that differences in problems be systematically explored given that exploration of the mathematical patterns found in solution strategies provides children with opportunities to construct a deep understanding of principles underlying mathematics, see [National Research Council 1989], [Steen 1988], and [Stone 1996b].

Knowledge Engineering Ontologies, Constructivist Epistemology, Computer Rhetoric: A *Trivium* for the Knowledge Age.

Arthur Stutt
Knowledge Media Institute,
The Open University, UK
A.Stutt@open.ac.uk

Abstract: In this (largely speculative) paper I want to suggest that certain ideas which have recently been developed by knowledge engineers can fruitfully be applied in the educational context. I have two main reasons for thinking that this is so: firstly, ideas from knowledge engineering have been applied in the past with some success; secondly, over that last five years or so there has been a paradigm shift in knowledge engineering away from a mining-and-transfer view of knowledge acquisition to a constructivist, modelling approach which has broad similarities to currently prevalent ideas in educational theory. Briefly put, knowledge engineering can provide the conceptual and other tools which can facilitate the construction of *knowledge models*. The relevant knowledge engineering ideas are illustrated with a knowledge model from the archaeology domain and the possible benefits for learners are outlined.

In this paper I want to suggest that recent developments in knowledge engineering have much to offer as the basis for a modern *trivium* which will enable learners to cope with the expansion in the availability of information. This *trivium* consists of ontological and other (problem solving) categories from knowledge engineering, a basically constructivist rather than mirroring approach to knowledge and, finally, computational models of argumentational structures.

The currently dominant educational paradigm of constructivism can be seen as the view that meanings and knowledge are constructed by learners actively interpreting their experience [Nicaise & Barnes 1996; Jonassen et al. 1993; Perkins 1991; Duffy & Jonassen 1991] usually in collaboration with other learners. Many constructivists also espouse the idea that students should be expected to cope with "authentic" problems; an idea from research on situated cognition [Brown, Collins & Duguid 1989].

At the same time there has been a move in knowledge engineering away from the view of knowledge as a stuff to be extracted and poured into representation formalisms to one in which the engineer, in cooperation with the expert and users, creates models of the problem solving activities in a domain. The KADS knowledge engineering methodology [Schreiber et al. 1993; Tansley & Hayball 1993] is centred on the development of a series of models.

For the constructivist educator, recent developments in knowledge engineering provide a set of components which can be used in knowledge modelling by learners. Since these modelling components cover both the domain contents and the problem solving which operates over these, they should provide a basis for student acquisition of domain knowledge (including problem solving) and meta-cognitive skills such as the selection of problem solving strategies. The tool I envisage differs from that discussed in [Conlon & Pain 1996] in that the full range of modelling components will be made available to students. This is partly for flexibility in modelling but also because it is more likely that problem solving and meta-cognitive skills will be acquired if a range of problem types and problem solving methods is encountered. The important components are outlined in the following:

Ontologies: Using air photo interpretation (of Romano-British archaeological sites) as an example, the ontology which is relevant to the domain is an intersection of the set of terms (and relations over them) for describing air photos (e.g., shadows, linear features, irregular features) and those for describing Romano-British building structures (e.g., domestic, military, commercial, fort, fortlet, camp). Ontologies provide the learner with a clear and consistent domain terminology which can be used in collaborative model construction, and a means of structuring the domain concepts in terms of relations.

Domain Descriptions: In accordance with the ontology as given above, the domain description consists of a series of instantiated relations. The construction of these will involve the learner in a process of knowledge acquisition (in the engineering sense). In archaeology, the outcome of the process will be equivalent to the section of an archaeological report which includes full details of some aspect of the archaeological record. In addition, the engineering process assists in the acquisition of various relations between concepts which would

BEST COPY AVAILABLE

not commonly figure in an archaeological report. This immersion of the learner in a domain should ensure that at least this static knowledge is retained.

Problem Solving Methods: Problem Solving Methods (PSMs) are templates which indicate the tasks to be carried out in a problem solution, the structure of these tasks and the types of domain items to be operated on. They are not algorithms for problem solving; in fact, many different algorithms can be derived from them. Given a view of air photo interpretation in which particular features (e.g., rectangular foundations) are evidence for particular archaeological structures when other evidence, such as the relation to other structures, is taken into account, the most suitable problem solving method here is Heuristic Classification. Heuristic Classification operates on Observables (such as the location of linear features) to produce Solutions (e.g. "This photo contains a Roman fort"). It does this by abstracting Observables into Descriptions (here lines, areas and air photo features are abstracted into higher level descriptions) and matching these to Abstract Solutions (here, descriptions are mapped to building structures). Whether constructed or retrieved from libraries, PSMs are especially useful since they are not usually recorded or represented in normal disciplinary discourse. In addition, while PSMs are primarily models of problem solving skills, it is possible to model meta-cognitive processes such as PSM selection and validation since these are also problem solutions.

Although there is a difference between knowledge engineering (where the goal is the production of models which can be used in the design and implementation of a fully working system) and education (where the goal is an increase in the ability of learners to differentiate between types of knowledge, to acquire new knowledge, to communicate about their knowledge and to apply their skills in real life situations), I would suggest that the following are the likely benefits to the learner in making use of knowledge modelling components:

1. Knowledge models can be collaboratively developed (i.e. constructivism in practice) with opportunities for student role-playing;
2. The model components and domain description vocabularies will provide students with a common language (which can be more or less precise depending on their educational level);
3. Students interacting with knowledge level models will come to understand that there are many different types of knowledge, that domain descriptions can be used for many different problems and that the same problem solving strategies can be used across a number of domains.
4. These models are useful as a means of learning domain contents, problem solving skills, meta-cognitive strategies and domain discourse(s).

A tool built using recent ideas from knowledge engineering is not only largely consistent with constructivist ideas, it may provide the means for achieving some of the larger ambitions of constructivist researchers (such as the development of meta-cognitive skills). I say "largely consistent" since I am unsure to what extent the modelling framework provided by knowledge engineering is flexible enough for truly constructivist modelling. I suspect however that some structure (and therefore inflexibility) is needed if an environment is to act as a modelling environment. Given this, it is largely up to the learner to acquire the modelling and other cognitive skills necessary for the effective use of the new tool just as medieval students had to learn logic, rhetoric and grammar. The question of whether knowledge engineering provides the appropriate structure will be resolved when a system based on these ideas is built and tried out by learners.

Using the Reeves and Harmon Instrument to Evaluate Interactive Multimedia

J.D.E. Thomas, Ph.D. and L.L. London, M.B.A.
Baruch College, Dept. S/CIS, 17 Lexington Ave, Box- E-0435, N.Y., N.Y.
Email : nifbb@cunyvm.cuny.edu or llondon@inch.com

Abstract: The Reeves and Harmon instrument, designed for use by expert designers and users of interactive multimedia (IMM), was tested with 5 CIS acedemics to determine its viability. These users found that the instrument required too much of a grounding in pedagogical priniciples to be usable by them.

1. Introduction

The lack of adequate instruments to assess ease of use or usability of software has been acknowledged in the literature. This poses problems for those who must try to assess and make choices from among competing packages especially when the application to be evaluated is an educational one and must take in the learning outcomes as part of the evaluation process (Kraiger, Ford and Salas, 1993). Reeves and Harmon (1993) developed an instrument for expert designers and users of Interactive Multimedia (IMM) which they feel can adequately elicit the subjective reactions of users of applications of this genre.

A computerized version of this proposed instrument was constructed using the authoring tool, Toolbook,with links to a database developed using DBASE IV. (Thomas and London, 1996). Five CIS academics were asked to use the instrument to evaluate an IMM CD-ROM used in an Introductory Multimedia course. The consensus was that the instrument was far too complex for use by them, requiring as it did the user to have strong grounding in pedagogical principles.

2. The Instrument

Reeves and Harmon's (1993) instrument suggests that multimedia instructional applications should be evaluated on 10 user interface dimensions - ease of use, navigation, cognitive load, mapping, screen design, knowledge space compatibility, information presentation, media integration, aesthetics, overall functionality, and 14 pedagogical dimensions - epistemology, pedagogical philosophy, underlying psychology, goal-orientation, instructional sequencing, experiential validity, role of the instructor, value of errors, motivation, structure, accommodation of individual differences, learner control, user activity, cooperative learning. These are assessed on various continua, rated from ten to zero.

A graphical representation of the matrices of both dimensions is similar, each being plotted on a set of continua that are measured on horizontal axes. The User Interface dimensions continua move from "Negative Design Principles" to "Positive Design Principles" in a leftward progression. Therefore, if an assessment graph tends to be more predominantly to the right of the matrix, the application can be assumed to embody better design principles than one whose assessment graph tends to be more to the predominantly to the left of the matrix. The Pedagogical dimensions continua move from what we call "Generic Learning" to "Individualized Learning". Therefore, if an assessment graph tends to be more predominantly to the right of the matrix, the application can be assumed to foster individualized learning, while if the graph tends to be more predominantly to the left of the matrix, the application can be assumed to foster generic learning. It is important for both the evaluator and the interpreter of the evaluation results to remember that while the User Interface assessment graph is a critique of the application, the Pedagogical assessment graph is a critique of its instructional content and approach to learning.

A clear strength of the Reeves and Harmon approach is that educational applications can *all* be assessed by the *same* criteria, thereby removing subjectivity and bias.

3. Pilot Study

The purpose of the study was to determine the viability of using the Reeves and Harmon instrument to evaluate IMM. Five CIS academics were asked to use the computerized version of the instrument to evaluate an IMM CD-ROM tutorial which came as part of a textbook used in an introductory multimedia course and to answer some open-ended questions

4. Results

Based on the assessment made by the authors of this paper, the IMM CD-ROM was judged to be average on all the User Interface dimensions. Pedagogically, it was estimated that it's design was based more on the Generic Learning model than on the Individualized Learning model. As a group, the raters agreed with the authors' assessments. More dimensions were rated as conforming to the Generic Learning model than to the Individualized Learning model. And, as expected, the Interface Design dimensions were all rated as average. In terms of the individual ratings given, however, a lot of variability was exhibited.

To the question on ease of completing the evaluation, three evaluators deemed it Not at all easy, one as Very easy and one as Easy. The overall reason for it not being easy to complete was an inability to fully understand the meaning of the dimensions. To the question of whether any other dimensions or criteria were missing, most expressed not being competent enough to answer the question, that is, not being a "learning expert".

5. Conclusion/Implications

Even with a small sample size, it is evident that the Reeves and Harmon instrument is too complex for use by end users untrained in the learning disciplines. The Pedagogical dimensions were particularly troublesome. As they note in their article, the instrument is designed for use by expert designers and users of IMM.

The sample solicited was unable to elucidate more appropriate criteria on which to make the evaluations. Could it be that the criteria used to evaluate textbooks might be a more appropriate basis on which to evaluate and compare IMM applications? That being the case, the content rather than its underlying pedagogical philosophy may be more meaningful. Issues such as completeness of material coverage, clarity, structure, lesson difficulty, use of examples and media, etc. may be more appropriate than whether the content is structured based on a particular pedagogical school of thought. Research in the area must continue to investigate these or other more appropriate criteria.

Expanding Horizons Via Telematics: an Interactive Process Among Children and Adolescents

Abstract: The purpose of this work is to present aspects observed in the communication of cerebral palsied children and adolescents with peers from other countries using internet. We think that such aspects are particularly important in the student's growing process within today's historical moment towards an "intercultural globalization". Some of the referred aspects are, among others, interchange of ideas and cultural and geographical information, motivation to learn more about their own context, attitudes of responsibility and autonomy, desire to expand their own horizons, respect for other ways of living, and valuing themselves.

The work developed at the Center of Informatics for Special Education of the Federal University of Rio Grande do Sul, south Brazil, has as its main focus to promote the interaction/communication among children and adolescents with cerebral palsy, from the state capital, Porto Alegre, and from other countries (Portugal and Canada). Collaborative activities such as newspapers and stories in addition to the interchange of messages about different topics have taken place. Within this context we have observed that in an initial stage, the students need to know more about their virtual pen-pals in terms of understanding more about their hobbies, families, schools, musical preferences, etc. In a later stage, this curiosity seems to move towards a wider scope - that is, the cities where the pen-pals live, local holidays, typical and regional food, turistic places and the most practiced sports.

An interesting aspect to be highlighted in this telematic interaction is the "break of frontiers" that seems to occur. The natural way through which these youngsters communicate among themselves, suggests that things such as nationalities and geographical and cultural frontiers are no longer relevant in the friendly relationship that emerges among pen-pals. Thus, the feeling of "becoming friend" to distant peers seems to occur due to commonly shared interests and the way in which these students express themselves in the messages sent. They seem to perceive one another just as new friends in distant places. They relate to one another with respect for their differences besides valuing themselves.

The communication among these youngsters through computer network seems to have fostered situations of permanent knowledge construction. Since the students wanted to share their own world, context, state, and country with their pen-pals, they began to pursue current and more accurate information on their own. They were also concerned about writing in a clear and correct way demonstrating attitudes of responsibility and autonomy. Thus, comparison and confrontation between the new knowledge and the knowledge the students already had, was a recurrent characteristic. This process provoked both the rise of new questions and the need for new explanations, which seemed to point out to sociocognitive conflicts.

Previously to such electronic communication, the youngsters already had preconceived ideas about the countries involved in the exchange. During the electronic communication, we could observe the students' interest in checking whether or not those ideas were correct. For example, the Canadian students thought that in Brazil, rain forests, wild animals and exotic indian tribes were part of the daily life of their Brazilian friends. They had also read that because of the high inflation in the country people were forced to get rid of the bills, burning them on the streets. The Brazilian and the Portuguese youngsters, on the other hand, found out that in spite of the fact that both groups spoke the same language, many words had different meaning in the two countries, and that the way in which some holidays were celebrated also differed. Furthermore, they became aware of the influence of the hemispheres in determining the different seasons. Messages from their web-friends in which the students referred to a season which was different from the one they were going through enhanced curiosity to know the geographical location of the countries involved.

In sum, our observations suggest that the interchange of ideas and information that takes place through computer network, can be extremely rich and occurs in a spontaneous and natural way, which makes them meaningful for those involved. The students' curiosity in relation to the expansion of their own world view, by getting to know other forms of living, respecting the differences, in a simultaneous process of acceptance and valuing of themselves, were remarkable characteristics. In addition, the students also felt motivated to know more about their own context, showing attitudes of responsibility and autonomy. Knowing how to efficiently communicate using new technological resources and learning how to expand the notion of local "community" towards a world level are crucial elements for a more relevant and meaningful performance in the current and future society.

Comparing a Text-based Intelligent Tutoring System to Intelligent Multimedia Software

Abstract: A three part empirical study is underway to determine whether or not college students can learn C pointers more effectively with the aid of computer software. Lecture alone has proven to be of little success in teaching these concepts to many students. The experiment consists of tracking the scores of novice C programming students on questions about pointers. The control group received lecture notes accompanied by classroom instruction. Treatment group one received the same notes and lecture but were introduced to a text-based intelligent tutoring system covering the basics of C pointers. Treatment group two received the same lecture and notes as the previous two groups, but was given the opportunity to use a multimedia version of the software. The experiment was carried out over three fifteen week semesters. This paper presents a summary of results obtained thus far, an evaluation of the software by the users, and compares the two tutorials.

Introduction

In an effort to help novice C students understand and use pointers correctly, two pieces of software were developed that focused on pointers. The first piece of software, CPR, C Pointer Remediation, is an intelligent tutoring system (ITS) that covers pointers to variables, arrays, and pointers to structures. The second piece of software, CPR_MM, is a multimedia version of the tutorial. Both tutorials contain the same pedagogy. Both versions teach identical concepts. It was our intention to offer these two tutorials to students in an effort to study the learning effects and use of the two versions of the same software, compared to students who learned pointers without the aid of software.

The Experiment

A three part experiment was initiated at Montgomery College in Rockville, MD. The control group (C) consisted of thirty-eight students who completed introductory C programming classes taught in the fall of 1995. This group received notes and classroom lectures, but no software to help them learn about pointers. The first treatment group (T1), derived from forty-two students who completed the classes during the spring of 1996, received the same lecture notes and were also provided with CPR, C Pointer Remediation, a text-based intelligent tutoring system. The second treatment group (T2), consisting of thirty-four students who completed C programming classes during the fall 1996 semester, had access to CPR_MM, the multimedia version of the software. All classes were taught by the same professor and used the same notes.

The subjects were not coerced, nor were they given any extra credit for using the software. It was our intention to give T1 and T2 subjects free copies of the software, for use on home computers. In order to obtain a copy of the software, the subjects were required to bring diskettes to the computer lab. CPR requires one high density diskette, can be run from either DOS or Windows, requires a PC with a minimum of a 80286 processor, and does not require installation on a hard drive. It uses menus and commands consisting of a single keystroke for navigation. CPR_MM requires four high density diskettes on which to store the compressed files, and a PC with a Windows interface, a sound card, a 80386 chip or better, eleven megabytes of hard drive space for installation, and a minimum of a VGA monitor. Navigation is by mouse.

CPR is the superior piece of software from a pedagogical standpoint. It detects all correct answers and the top four incorrect answers to questions generated by the software. It has a student model that estimates the amount of knowledge that any user possesses on a given concept. It contains a module that allows the user to type a function as if in the editor of a C compiler. The multimedia version, CPR_MM, written in an authoring system, contains the same concepts and wording, but is not an ITS. However, it contains sound and animation. It does not have an accurate student model. Additionally, because of limitations imposed upon the programmer by the authoring tool, each correct answer must be added to the system individually. Therefore, CPR_MM does not necessarily detect all of the numerous correct responses. Some responses can not be typed at all, due to idiosyncrasies of the authoring system, and must be stored as multiple choice type answers.

Each treatment group was exposed to only their particular version of the software. Each subject evaluated their software and chose whether or not to obtain a copy. The ratings of both versions of the software were good. On a scale of 1 to 5, with 5 being the top score, the average rating of CPR was nearly 4.0; that of CPR_MM was .5 higher. However, the number of students who reported actually using the software was rather disappointing: 40 percent (17 of 42 CPR subjects) and 38 percent (13 of 34 CPR_MM subjects). . It should be noted here that one reason that the numbers were so low may be that the subjects in the experiment were those still enrolled in the course at the time the final exam was administered. There is approximately a fifty percent dropout rate of students in this programming course. It is possible that the students more likely to use the software, i.e. the less confident students, were eliminated by the end of the study because they were not present to take the final exam or answer the final software usage questionnaire.

Subjects were tested six times over the fifteen week semester. Those who did not use the software scored nearly eight points better on their midterm exams, administered prior to the introduction of the software, than those who used the software. A statistical analysis of the five measurements following the release of the software indicated no statistical differences in scores between any of the groups. However, CPR users reported that they used the software an average of 4.1 hours; CPR_MM users reported 4.6 hours of use. Non-users of the software reported that it took them between 2 hours and 2 months to learn pointers. CPR users were about three years older than the non-users. There was no difference in the ages of users and non-users of CPR_MM. The students who used CPR tended to be poorer students than those who did not use CPR. There was no apparent difference between type of students who used or did not use CPR_MM. At the end of the semester, the CPR software was rated higher, by 4 tenths of a point, than the multimedia software in response to how well it helped the students learn C pointers.

Who actually learned more? The multimedia users, who spent more time using their software, and had the benefit of animations, actually pulled their scores closer to those of the control group than the ITS users. We were surprised at these results because the ITS was clearly the better software from the point of view of the educator. However, it was more difficult for the subjects to use. The CPR users had more trouble with disorientation compared to CPR_MM users. The CPR users were also less enthusiastic about the software than the CPR_MM users.

Given the high ratings of the software, we were surprised that more subjects did not report using it At the end of the course, we asked the multimedia group to choose which method of instruction they preferred. Seventy three percent of them said they would rather have an instructor, eighteen percent chose the software, and only nine percent chose a combination of software and instructor. Given the general attitude among educators that software is going to be a big boon to learning, we did not expect these answers. It seems that, at least among college aged students, there is not a great deal of confidence that software helps one learn. However, the evidence suggests that students learn as well using software as they do with any other method.

Gaining Practical Experience through a Media Mix Course in Environmental Chemistry

Jan van Laake, Utrecht Polytechnical School, Technical Faculty, Dept. of Educational Development,
email: J.vanLaake@staf.fnt.hvu.nl

Rien van Stigt, Utrecht Polytechnical School, Technical Faculty, Dept. of Educational Development,
email: R.vanStigte@staf.fnt.hvu.nl

Abstract: Inorder to make students gain experience in solving practical problems in the field of environmental hygiene a course was developed by a team consisting of both teachers and experts, working with engineering companies and research institutes. The resulting course was a multi media mix centered around existing computer software used by the experts. These experts also markedly influenced the content of the course. The result is a wide variety of student activities in the course and a high appreciation of the topics by the students. The course is still developing and new media are being used to enhance efficiency and effectiveness.

Introduction

In the first years of the educational program students say: "It is all a lot of theory, what about real life practice?" And, for example during internship with an engineering company, a government agency or a research institute, we hear professionals say: "These young engineers do not know where to begin when facing a professional problem and they cannot even write a proper report, let alone present it in an orderly way".

In an attempt to present a true image of environmental engineering practice, we integrated the necessary theoretical concepts that we already used to teach and at the same time enabled students to practice skills in both problem solving and presentation. In the Department of Laboratory Research of our institute the existing course in Environmental Chemistry was found to lack sufficient links to real-life environmental problems. The idea arose to develop an interactive video program on environmental chemistry. The result however ...

Objectives, means and media

Environmental chemistry studies behavior and fate of pollutants in the environment and the methods that can be used to identify and measure these substances in air, water and soil. Pollutants are emitted into the environment, transported by wind and water and in the process they are being altered by physicochemical and biochemical processes. Environmental chemists work in multidisciplinary teams together with e.g. civil engineers, toxicologists, experts in urban planning and juridic advisors. Together, they assess the risk of past or future pollution and suggest and implement ways of remediation and prevention.

The project team decided to first define the objectives of the course and only after that decide which means or media would be apropriate to realize these objectives. The new course was developed to enable students to:

- solve "real-life" problems in the field of environmental chemistry and environmental hygiene;
- understand and apply the theoretical concepts in environmental chemistry concerning the most common pollutants' effects in the environment and their behavior;
- get acquainted with the ways in which professional environmental engineers tackle pollution problems;
- value the multidisciplinary character of environmental engineering.

In view of the proposed integration of environmental chemistry into the whole of environmental engineering, the course was given the title "Applied Environmental Chemistry".

Development: the role of the experts

Professional environmental engineers were asked to design one module of educational material around a case study, obtained from their own experience. They were only given a theme and a set of objectives, serving as design specifications. The project team anticipated that all experts would want to alter the objectives given by the project team, which they did indeed. A good deal of our original objectives, however, was not altered.

Also with respect to educational media, other than professional simulation programs, our contacts with companies and research institutes proved to be very useful: we came across a promotion video tape that, at first glance, would be eminently suitable to be used as an introduction in problem solving in the field of soil contamination. Indeed, the problem presented was used as the case study in the first, indroductory, module. In cooperation with a company that develops and sells soil research equipment, we realized a slide show on soil drilling and sampling.

But the most important contribution the experts made to the course was the emphasis they put on all kinds of practical details, having to do with organisation, management, cost and environmental policy. By doing so, they made far more clear than the project team had expected, the importance of a multidisciplinary approach of environmental problems and of skills our students should practice in the field of project management.

Student activities

Now, what are students supposed to do in this course of Applied Environmental Chemistry? All modules present a problem in the form of a case study. In a more or less guided tour around this problem, students use a specific heuristic to solve it. This heuristic for problem solving consistis of the following steps:

- description of the problem: what's the situation?
- analysis of the problem: causes/results and boundary conditions.
- generation of possible solutions.
- selection of the "best" solution.
- implementation of the solution chosen.
- report and evaluation.

Multi-media?

We looked for the best media to achieve the established objectives in the context of the type of education where the course would be used. The result was a mix of old and new media. Where we wanted to purely transfer information in word and writing that could easily be presented in a lineair way, paper appeared to be the carrier of choice. Understanding processes requires moving images or combinations of image and sound, in which case the use of video, slides or multimedia programs is obvious. We also incorporated some existing audiovisuals into the course in order to achieve an attractive mix of student activities. The use of computer simulation was apropriate to make students visualize and handle theoretical concepts in real situations as presented in the cases. The resulting mix of student activities was developed at relatively low cost, was easily implemented in various departments of our institute and in other institutes and was easily accepted by teachers because of its open and modular structure. Furthermore, it is flexible and teachers can adapt and extend it with their own means, as e.g. a supporting web site on internet.

Since the course Applied Environmental Chemistry was only started formally in september 1995, it is only possible to draw some preliminary conclusions. So far, it turns out that students are highly motivated to solve the problems presented in the modules they use in class. Only in a few years time we will be able to state wether or not students show a more professional attidude towards problems they face during internship or in their first job. Teachers agree on the following points:

- cooperation with experts in developing the modules was instructive and motivating.
- case studies present a true mirror image of every day engineering practice.
- contacts with professional authors paved the way to state of the art educational materials.

PLAN-PILOT-PRODUCE-PROBE: A MODEL FOR DELIVERING SYNCHRONOUS AND ASYNCHRONOUS DISTANCE EDUCATION

Mary Wall, Ph.D.
Associate Dean
Atlantic Community College, Mays Landing, NJ ,USA
wall@venus.atlantic.edu

Joyce Grohman, Ed.D.
Associate Dean
Atlantic Community College, Mays Landing, NJ, USA
grohman@nsvm.atlantic.edu

Abstract: Atlantic Community College has a college-wide planning process. One of the goals developed in the plan is: "To enhance classroom instruction through the exploration and integration of appropriate informational technologies and pedagogical techniques while maintaining the personal aspects of education necessary to community college students." Because access is a problem for many community college students, the college decided to use technology to offer courses in a distance education format. We decided to offer courses in both synchronous, real-time video format and in asynchronous, computer-mediated format in Fall of 1996. In order to do a quality job we decided to plan first, then pilot, then evaluate, and finally incorporate the technology into courses for the entire college.

PLAN

Planning involved selecting the courses and teachers and securing the proper hardware and software. In this presentation, we would like to present the model used: the forms developed and the decision process. The courses selected for the pilot were elective courses, because we did not wish to have students new to the college or students in required courses deal with the new technology. The two presenters were selected as part of the pilot faculty.

Securing the hardware and software involved working with external agencies. The State of New Jersey provided money for every college in the state to set up a room capable for the delivery of live, full-action video. There was no money and no infrastructure to connect the rooms. The college used a Challenge Grant to equip a second room at a satellite campus so that courses could be delivered simultaneously at both sites.

For the asynchronous course, FirstClass software was selected. Students were told that they must have an Internet provider to join the course and that the college would provide no help with hardware problems. The Student Services area of the College was kept aware of developments in the planning phase, and the pilot courses were clearly noted in the tabloid. A handout was prepared for the counselors so that they could answer student questions.

BEST COPY AVAILABLE

PILOT

The courses piloted were Financial Accounting and Nursing Management in the synchronous area, and Self Management, a liberal arts three-credit psychology course, for the asynchronous mode. The Nursing Management course was taught by presenter Joyce Grohman and another faculty member. The Self Management course was taught by presenter Mary Wall, also with another faculty member.

The faculty were identified ten months before the pilot began. That time was devoted to preparing the syllabus, course activities, and evaluation. Every effort was made to incorporate collaborative learning activities in the classes. The resulting materials were extensive and detailed.

This presentation will deal with the successes of the pilot courses, and the difficulties encountered. Successes included student response, course design, and enthusiasm of the student and teachers in the pilot. Difficulties included problems with the hardware and software, the time involved in developing the courses to use the new technology, and initial adjustments that had to be made in learning in a new environment.

PROBE

Student evaluations were conducted at the end of both classes and will be shared at the conference. Reports were written by the teachers of the pilot classes, with recommendations for improvement.

In Spring 1997, Introduction to Literature was offered in the synchronous classroom, and Communications 1, Communications 2, and Special Topics in Literature were offered in the asynchronous mode.

SUMMARY

While distance education is in keeping with the mission of the community college, it involves a major shift in the allocation of resources. The entire college must be involved in the effort: the Information Technology area, the faculty, the administration, and the counseling office. Only by involving the entire college community can the effort succeed.

We were happy we began with elective pilot courses. Students in these courses were mature adults, who could adapt to initial problems with hardware and software. The faculty selected were experienced teachers, who had many years of teaching at the college and were willing to take chances.

Evaluation formed the closing of the cycle. As distance education becomes more common at the college, the lessons learned in the initial pilot will be routinely incorporated into the process. In this session we would like to share with others considering distance education the model that we used and the lessons that we learned.

The TEAM Project: A University - Public School Collaborative

Marrion W. Ward
Appalachian State University/Public School Partnership TEAM Project
Appalachian State University, USA
wardmw@appstate.edu

Abstract: The TEAM Project employs Appalachian State University faculty and graduate students to support teachers in a seven county Partnership as they integrate computer technology into their daily classroom activities. The TEAM Project provides hands-on workshops for teachers from 85 schools, Internet connectivity, free access to e-mail on the university mainframe computer to the 2,500 teachers in the Partnership, model teaching, and graduate students in computer technology who work one day a week for one semester in a school. The Project has evolved from an emphasis on large group training to an emphasis on in depth training for smaller numbers of teachers.

The TEAM Project at Appalachian State University in Boone, North Carolina, is in its fourth year of planning and executing staff development in computer technology and its integration in the classroom. The Project serves teachers from a seven county area comprising the Appalachian State University/Public School Partnership. During the first three semesters, the focus was teaching telecommunications, databases, and spreadsheets to large groups of teachers in each of the Partnership counties. However, beginning with the 1995 fall semester, the approach changed to targeting a small number of teachers and working in depth on telecommunications applications for both classroom use and for professional development.

Technology Contact People

Each of the 85 schools in the Partnership has designated a technology contact person for TEAM. This person is a classroom teacher rather than a computer technology specialist. The technology contact person's responsibilities are to attend three five hour workshops at Appalachian State University, to develop and execute lesson plans incorporating computer technology into their teaching, and to visit the TEAM homepage each week in order to disseminate relevant teaching information to co-workers. TEAM awards each teacher a stipend of $100 per workshop.

All workshops accommodate teachers with various levels of computer skills. The first workshop focuses on the use of electronic mail. Novices learn such activities as logging on, accessing and sending mail, and creating an address book. More advanced users learn how to append and access attachments to e-mail. The first workshop also includes guided practice in navigating the Internet including bookmarking, using search engines, and printing. The second workshop highlights using the Internet to access sites which can be used in each teacher's current curriculum area. Round table discussions provide a forum for teachers to share ideas about using computer technology in the classroom. The third session provides guided time for each teacher to prepare a lesson using Internet resources. A culminating activity allows teachers to share with each other the lessons they have designed.

Continuing Support

The TEAM Project continues a relationship with the technology contact people by sending them weekly electronic messages encouraging them as they incorporate the computer into their teaching and inviting them to share creative ideas on a wide variety of subject areas. The technology contact people as well as other teachers in the Partnership have the opportunity to join a listserv to which they are invited to pose questions, list helpful websites, and post calls for collaboration.

During the 1997 spring semester, TEAM is sponsoring two collaborative endeavors. The first is a weather project to which each participating classroom sends information about area weather conditions at specific times of the day. Those data are compiled and posted on the TEAM webpage. A second project involves students' submitting information about their community including a description of the community along with a brief history told to the students by an elderly citizen.

Other Workshops

Team offers special interest workshops for teachers. Website construction has enabled a number of schools to produce vanity pages on the Reich College of Education fileserver. TEAM also conducts introductory and advanced workshops on installing and navigating Windows 95. Additional workshops provide instruction to public school principals, superintendents of the Partnership counties, and administrative assistants from each central office. Each workshop is tailored to the specific needs of the group to facilitate communication between people of like responsibilities and to identify resources available to administrators.

Connectivity

In 1994, the project offered toll free access to Appalachian State University's mainframe computer for 2,500 school personnel. That connectivity gave them access to all the distance resources available to the university. As teachers requested graphics rather than text only and as TEAM's toll charges began to increase with the expanding teacher use, TEAM funded Internet access through local providers. Funds were available for connection for only four schools in each county. Negotiations with local providers resulted in their offering free service to schools in four of the seven Partnership counties. TEAM then purchased connectivity with local providers for all of the schools in the remaining three counties for one semester. At the end of that time, each school's personnel evaluated their use of the service and decided whether or not to pay for connection themselves. Then the toll free 800 access to the university's computer system ended.

TEAM maintains a website that is updated weekly. A new "Link of the Week" appears each Monday. These links are chosen because of the sites' potential for use in the classroom. Data from collaborative projects are posted on the page as well as links to course offerings in technology for teachers by local community colleges. In addition, the site provides administrative resources and links to lesson plans for a variety of subjects..

Internships in Schools

Technology Coordinators in each of the seven school systems choose one school to host a graduate student in computer technology to work in that school one day a week. The main component of the graduate students' duties is working with teachers to plan lessons integrating computer technology in their curriculum. The students help locate resources for the teachers, co-teach the lesson, model teach the lesson for the teachers, or trouble shoot technical problems that may arise while the teacher is conducting the lesson. The graduate students also work with teachers individually or collectively to teach button pushing skills or develop collaborate teaching units. The sustained presence of the graduate students throughout a semester has enhanced and expanded the use of computer technology by both teachers and students.

Lessons for Staff Development

The TEAM Project has found that planning for staff development that results in teachers using computers effectively and comfortably in their teaching must incorportate the following three areas. The first area is the number of participants in each staff development session. A series of workshops with no more than 15-17 teachers provides participants sufficient technical and integration skills to use computers consistently and effectively in their classroom. Workshops with a larger number of participants often do not provide enough individual attention for teachers to carry the learning into effective teaching practices. The second area is sustained contact with teachers after staff development workshops. For the first three semesters, TEAM maintained a toll free help desk for teachers with questions. On-site help, however, has proven to result in greater teacher satisfaction. Graduate interns in the schools have been a key to substantial qualitative and quantitative use of computers. The final area is providing collaborative opportunities for teachers. Collaboration between teachers at the computer as well as collaborative projects for students has increased the enthusiasm and comfort level of educators as they use computers in their teaching. The TEAM Project continues to evolve in its approach to designing staff development. Its primary commitment, however, is support for teachers that results in enhanced learning opportunities for students.

An ITS for Guiding Fraction Calculation using a Pen-Computer
– Handwriting Character Input Interface and Its Evaluation –

Kenzi Watanabe[†] Hirotaka Sasaguri[‡*] Yasuhisa Okazaki[‡] Teisuke Yamaguchi[‡]

Abstract: This paper describes an implementation of an ITS for guiding fraction calculation using a pen-computer and evaluation of its interface. By using a pen-computer, our system has following distinctive features; (1) handwriting character input with its recognition, (2) direct pointing and (3) gesture function for fraction correction. The handwriting character input with its recognition using a pen enables students write fractions easily and naturally as if to use a pencil. The direct pointing function enables students fix input point without moving a cursor. The gesture function contributes easy fraction correction. The results of evaluation experiment show these distinctive features work well.

1 Introduction

We have developed an ITS for guiding fraction calculation. This is a drill type ITS. Distinctive features of the system are that it can recognize student's context of solving processes and guide them in accordance with their context [Watanabe, 1994].

Recently, there are a lot of products that make use of a handwriting character recognition and liquid crystal technologies such as a pen-computer. We have made use of advantages of a pen-computer to our system as an interface. This new system has following distinctive features; (1) handwriting character input with its recognition, (2) direct pointing and (3) gesture function for fraction correction.

This paper describes an implementation of an ITS for guiding fraction calculation with handwriting character input interface and its evaluation.

2 Outline of the system

The system is implemented on two computers. One is a pen-computer (SANYO MBC-MP100J), the other is UNIX workstation (Sun SPARC station 5). The pen-computer plays a role as an interface. The UNIX workstation has intelligent modules. These two computers work together.

3 The interface

[Figure 1] shows the display of the interface. A student can write fractions using a pen into the input field which is presented in the left side of the display. When a student writes numerical characters and other symbols such as '+' and '−,' the system starts to recognize the character. If the system succeeds in recognition, recognized character is shown in the same place. If the recognition fails, the system erases the handwriting. So the student has to write character again.

The system has two special functions for fraction correction. One is "overwriting," the other is "gesture function." The overwriting function replaces a character on the display. We define some special handwriting symbols as "gesture." When a student writes a gesture, the system executes a function bound with the gesture. The system has two types of gesture, "erase one character," and "erase whole fraction expression."

Figure 1: The interface

4 Evaluation of the interface

We had an experiment to evaluate the fraction input and correction of the pen-computer system. In the experiment, students tested three systems (1) the pen-computer system, (2) the keyboard system and (3) the pencil and notebook. Amounted 38 students joined the experiment. After using all systems, students answered to a questionnaire.

74% students felt better the pen-computer system than the keyboard system for fraction input operations. Advantages of handwriting character input with its recognition and direct pointing function reflected the result.

Although students used the same medium at using the pen-computer system and the pencil and notebook, 79% students felt better the pencil and notebook than the pen-computer system for fraction writing. We think that there are two reasons, both of them are technically solvable. We are going on an improvement. These problems will be solved in the near future.

76% students felt better the pen-computer system than the pencil and notebook for fraction correction. Because the system doesn't need to use an eraser. This advantage enables students to correct easily and quickly.

On the keyboard system, students have to move a cursor to the point where they want to correct. However, the pen-computer system doesn't require these efforts to the contrary. 79% students felts better the pen-computer system than the keyboard system. The result shows this advantage. The gesture function is also work effectively. It contributed easy fraction correction. A lot of students commented on it.

5 Conclusion

We have developed an ITS for guiding fraction calculation using a pen-computer. This system has following distinctive features; (1) handwriting character input with its recognition, (2) direct pointing and (3) gesture function for fraction correction to the system. The results of evaluation experiment show these distinctive features work well.

We are going on an improvement. We are planning a field test of the pen-computer system. These are future issues.

Concept of the Project MILES

The multimedia database system MILES (= *M*ultimediales *I*nformations- und *LE*hr*S*ystem), the first of its kind in Europe, has been developed in the Department of Physiology, University of Essen Medical School, in two stages since 1980 [Wiemer et al. 1989, Wiemer 1997]. The field test of the PC-version began in 1989/91 in connection with teaching physiology to 160 students of medicine per year. Since 1993, MILES has been employed in all types of classes as well as in individual studies independent of classes. By the beginning of 1998, most of the curriculum subject matter provided by the department will be covered by the system. The primary aim of this project is not to produce single teaching units, such as particular simulations or tutorials, but to use this system as a *common source for all computer and audiovisual materials* over the entire curriculum in physiology.

Configuration: The *hardware* consists of a network of personal computers (386/486 compatible, SVGA 1024 x 768, operating system PC-DOS), supported by servers, and connected to various input/output and storage devices. The *software* is built around a text processing *database*, containing all text sections of documents as well as the control information about all non-text materials in store. The user also possesses a *personal base*, to which data and program references can be transferred from the main system by a standard command; thus students can build up data collections and learning programs of their own.

Materials: Up to now, more than 9000 documents have been stored including data processing programs, simulations, signal recordings, video and audio modules, about 3000 pictures, a glossary of physiology with several hundred entries, and a collection of more than 3000 test questions. Only part of this material was produced in the institute, the rest acquired from external sources.

Teaching units. The units compiled from these components are structured differently, depending on their curricular affiliation (lecture, seminar or practical) and level of comprehensiveness required by their contents (for example, whether they treat new topics, or present just supplements to matters generally available from text books). Altogether, the system provides materials for the following main applications: a) *demonstration in lectures and seminars,* b) *work in seminars and practicals,* c) *individual studies independent of classes* at terminals in the institute, d) *studies at home,* for which units will be offered from 1997 on.

Experiences and Problems

System performance: Our expectations in regard to power, versatility, flexibility and portability of such "open" multimedia systems have been fully confirmed, the teaching concept has proven realizable. Current problems no longer arise from hardware, but from *software,* from *application concepts,* and from *production of teaching material.*

Acceptance by students: MILES has been accepted by students well, and was, in part, rated even higher than the accompanying personal teaching. However in practice, this positive attitude held true only as far as computer-based materials had been presented in seminars and practicals, that is, *had been integrated in personal teaching,* *and contained obligatory subject matter* examined thereafter. Only here our students made intensive use of system materials. There was significantly less interest for materials from lectures, which are neither obligatory nor connected with examinations. The acceptance was extremely poor for materials offered *in bypass to classes as mere self education programs.* The majority of students considered these new media altogether as *very useful, but not necessary,* i. e. lastly as a superimposed teaching, not professionally required, technology.

Concepts for future application of multimedia systems in medicine: These are still controversial, ranging from mainly computer-mediated curricula to merely focal integration into traditional teaching and learning. Since *direct experience with patients under the guidance of personal teaching will remain indispensable,* "virtual" medical schools are certainly unrealistic. Thus, *integration into* - however changed, but further existing - *personal teaching and into books appears to be adequate for the new media in medicine.* The domains may be expected to be a) *databases,* also providing general availability of pictures, films and signal recordings, and furnishing components for local composition of teachware, b) *simulations* of biological functions, of skills and practices, and of diagnostic procedures, using increasingly interactive video and CAD-techniques, c) *tools* for acquisition and processing of data of all kinds, d) *test materials* for evaluation of knowledge and skills, utilizing also multimedia techniques, e) *"open" authoring systems* for the local composition or adaptation of demonstration and teaching units, f) *tutorials,* for which, however, we see in view of good text books no exhaustive need.

The production problem: The most severe handicap for the broad introduction of computer media into teaching and learning in physiology proved to be the general *lack of materials,* especially those meeting high academic standards - not only of proper programs (such as tools, simulations), but also of components (such as bases of picture and film collections on disks) suitable for building up individual teaching units. Offers *on the market* are still minimal. On the other hand, possibilities of *individual staff members* for the production of good teaching material are very limited, due to the high expenditure of expert time and technical know-how. Especially detrimental is the present *copyright situation.* The lack of a general copyright for acquisition and transfer of educational material by electronic media prevents the exchange between institutes of material collected individually from commercial sources, such as figures from scientific literature, or films. As a consequence, systems like MILES are, at present, *not transferable,* since most materials cannot be transferred along with the software.

Acceptance of the new media by the academic staff: This is, on the whole, still unsatisfactory. Typically, just the prominent scientists do not participate in the production of media, at best they write text books. The situation is especially crucial for the junior staff, since in university systems as the German, academic career depends on merits of research, not of teaching. Consequently, there is a discrepancy, typical for the situation, between impressive reports on symposia and conferences about progress of system performances, and lack of use on the teaching level. Improvement can be expected only from the establishment of *broad systematic production of material* in co-operation between groups of authors, institutions, and commercial producers. So it may last another decade until the new media - already proclaimed overall victorious - will really have conquered higher education in medicine.

Abstract: This presentation describes the authors' experiences developing and teaching the first two computer mediated courses in an innovative Master of Continuing Education program at the University of Calgary in Alberta, Canada. Each course included: pre-session readings and orientation assignments, explicit learning goals and objectives derived from both students and overall program goals, systematic weekly agendas, interactive assignments, learning journals, small virtual group and/or dyadic exercises, flexible assignments, and on-line access to library resources. The instructional plan was organized around fulfilling four moderator functions: pedagogical, social, managerial, and technical (Berge, 1995). This paper focuses on how the authors' experiences with CMC did not always coincide with the oft-cited benefits and challenges of teaching in this medium described in the research literature. The authors feel that the partnership of computer technology and adult education has tremendous potential for re-conceptualizing the roles of instructor and student only if a significant investment is given to it by all stakeholders: instructors, students, technical support staff and program administrators.

The Benefits and Challenges of Teaching via CMC

In the relatively short time that computer mediated teaching has been available, several studies and literature reviews have pointed to a number of benefits and challenges of this mode of teaching (Burge, 1994; Gerein, 1995; Harasim, 1987; Hiltz, 1990; McCreary & Van Duren, 1987). The authors' experiences with teaching two pilot CMC courses in a new graduate program did not always coincide with these cited benefits and challenges in particular: higher level of participant interaction; higher quality of learning; access to more resources; technical difficulties; time-committment required by all participants; and miscommunication.

Reflections on the Benefits

A higher level of participant interaction, or interactive 'dialogue', did not always materialize. Many students reported a sense of 'monologue' instead of 'dialogue' and frustration with a lack of connectedness to classmates.

While the quality of learning did not suffer, CMC did not appear to afford as high a quality of learning than that experienced by both instructors in comparable face-to-face learning environments. However, the non-synchronous, text-based nature of CMC appeared to benefit less assertive/more reflective students (particularly female) who responded positively to the increased time to think and edit their on-line contributions.

CMC does allow for more access to a variety of library and internet resource. Not all studnets had the necessary time or technical expertise to take advantage of this feature.

Reflections on the Challenges

The technical difficulties encountered, which far exceeded both instructors' and students' expectations, were exacerbated by totally inadequate technical support.

CMC, as a text-based medium, required a far greater time-committment by both instructors and students. This unexpected additional time requirement was a major source of frustration and conflict for many.

Learning to communicate effectively without benefit of visual/auditory cues was particularly challenging for novice CMC participants, often resulting in still additional on-line time to clarify misunderstandings.

Conclusions Reached

Overall, these instructors found that one key distinguishing factor of quality face-to-face and on-line teaching, was a dramatic shift from a traditionally instructor-centered and authoritarian classroom towards a more student-centered, collaborative and egalitarian learning environment.

Abstract: The Virtual Gorilla is an immersive educational tool to aid in the instruction of K-12 grade students in the understanding and appreciation of animal behavior and issues of animal conservation. Through this immersive technology children can "be a gorilla," and experience "first-hand" what it is like to join a gorilla family group. VR technology has the potential to be a powerful tool in experiential education, in this example, sensitizing children to the gorilla world and giving them an understanding of the behavioral interactions that create gorilla society.

The Virtual Gorilla is an educational tool being developed by researchers from the Georgia Institute of Technology's Graphics, Visualization and Usability (GVU) Lab and PhD program in the College of Architecture in conjunction with researchers and staff from Zoo Atlanta. As a part of established Zoo Atlanta conservation efforts, the Virtual Gorilla project is being developed as an immersive education tool to aid in the instruction of K-12 grade students in the understanding and appreciation of animal behavior and issues of animal conservation.

The VR gorilla environment allows us to extend the educational experiences provided in the traditional zoo environment. A primary goal of Zoo Atlanta is to increase public awareness and involvement with issues of conservation. Through this immersive technology children can "be a gorilla," and experience "first-hand" what it is like to join a gorilla family group. They can "test" behaviors and elicit appropriate responses from other members of the gorilla family. We have been working with Zoo Atlanta staff not only to provide a realistic representation of the gorilla and the exhibit habitat, but to realistically portray the behavioral actions and reactions of the family group members, including motor behaviors and vocalizations. We expect this will be a powerful experiential educational tool in sensitizing children to the

Research on effective learning experiences suggests that this participatory environment will enhance and reinforce children's learning [see Bosco 1986; Fletcher 1989, 1990; Stafford 1990; Verano 1987]. Participatory experiences have been shown to increase motivation and retention of information. Entering the gorilla world captures a child's attention. Participation brings involvement and motivation to explore. This opportunity to "role play" provides each child with his/her own individual experience, one that is tailored to the interests and experience of the particular child, and one that may be different each time the child participates. This freedom to create a unique zoo experience, contributes an element of the unexpected, again an enhancement to learning.

The VR Gorilla Exhibit is a Virtual Reality representation of a real Gorilla Exhibit at Zoo Atlanta. Data provided by Zoo Atlanta includes actual terrain elevations, texture maps of foliage, and blueprints and site measurements of architectural structures. The modeled environment consists of the four main gorilla habitats, two auxiliary habitats, visitor pathways, exhibit areas, as well as the night holding facilities of the gorillas. Georgia Tech's Simple Virtual Environment (SVE) Toolkit is used to create an interactive, real-time virtual environment for exploration and learning.

The virtual gorillas are modeled based on anthropomorphic data from Zoo Atlanta. The gorilla model currently consists of 10 body parts and 9 joints with a total of 20 degrees of freedom. Motions are keyframed. The keyframes are generated from video of actual gorillas at Zoo Atlanta, and from behavioral data of gorilla movements. Keyframes currently illustrate characteristic locomotion modes and stances, such as walking on four or three legs, standing, squatting, lying down, staring aggressively, and chest-beating.

Gorilla behavioral data is derived from field notes and documentation gathered by Zoo Atlanta Researchers. This data was used in conjunction with expert advice from the zoo researchers who detailed behaviorial actions and reactions. (Some times even re-enacting the behavior on site, for Georgia Tech researchers!)

Currently users assume the identity of a juvenile gorilla within the simulated family. Beginning in the gorilla observation pavilion, the user become familiar with their environment and means of locomotion (currently gaze directed, frontwards and backwards movement). Once comfortable within the environment, the user will then pass `through the glass' and into the gorilla environment. Once on the gorilla yard, the user is restricted in movement only to that of the real gorillas at Zoo Atlanta (single yard, only terrestrial movement, though they can `climb' in and out of the moats separating the yards). The user may to explore the moats, rocks and trees, or attempt to interact with the other family members roaming the yard. The manner in which they approach the other members of the family group is monitored and appropriate response behaviors are elicited from other members of the family group.

Further development of the project will include expanding the behavioral repertoire of the animals to create a more realistic representation of the complexity of the gorilla society. A recurrent comment from the children who were involved in the demo was their interest in having a 'child' gorilla to interact with. This is one of our priorities for further development. The advantage of a young gorilla is that they tend to display a more varied and playful array of behaviors. The older gorillas are not very active. Although this is realistic, the kids entering the gorilla world are looking for more action. A young gorilla would provide this activity.

As the project is updated we will continue to work with groups of middle school students and their teachers to obtain feedback as to its potential effectiveness as a learning tool. This immersive environment will also be developed as a tool for zoo visitors to have an opportunity for a behind-the-scenes looks at the gorilla facilities. Visitors will be able to explore areas of the gorilla domain, such as the night quarters, that are ordinarily off limits. Explanatory information will be provided, as well as interfaces to access further information about the different care, conservation and research activities of Zoo Atlanta.

A Multimedia, Professional Development Program in Technology Enhanced Instruction

Janice E. J. Woodrow, Department of Curriculum Studies, University of British Columbia, Canada.
woordrow@unixg.ubc.ca

Gordon Spann, H. D. Stafford Secondary School, Langley, B. C. Gordon_Spann@mindlink.bc.ca

Abstract: The rapid influx of technology into education has increased demands for effective professional development in the use of new learning technologies in the classroom. This paper describes a CD-ROM based, professional development model designed to guide teachers in the effective classroom implementation of Technology Enhanced Instruction (TEI). The model is based upon the results of a four year field study of technology implementation in secondary science classrooms and includes exemplars of successful TEI teaching and learning strategies.

Background to Model Development

Technology Enhanced Instruction (TEI) is instruction in which computers, multimedia technology, telecommunications, and related resources are used to aid student learning and access to information. The TEI Professional Development Program described in this paper emerged from a longitudinal research program called TESSI (Technology Enhanced Secondary Science Instruction) [Woodrow, Mayer-Smith and Pedretti, 1996]. TESSI was designed to systematically integrate computers, multimedia technology, and related resources with elements of exemplary instructional practice to create a model of Technology Enhanced Instruction for science education. In each of the last four years, TESSI has produced increased learning outcomes and more positive student attitudes towards science and technology, and is in a unique position to guide teachers in effective classroom uses of technology.

Objective and Rationale

The objective of the TEI Professional Development Program is to help teachers learn to implement successful TEI teaching and learning strategies. [Gunter and Murphy, 1995] suggest that a major reason that education has been slow in implementing TEI is that "teachers have been involved in insufficient professional development/inservice activities regarding effective classroom usage of technology". How does a teacher learn to become an expert with TEI? Most technology training programs for teachers are aimed Level I Training: the development of foundation computer-use skills. While such training is necessary, it is not sufficient. Too often, upon the completion of training sessions, teachers are left on their own to figure out how to use new skills to enhance learning; no provision is made to address the fact that innovative and effective classroom uses of technology require revisions of teachers' and learners' educational practices. As computers and information technology become more fully integrated into classroom practice, teachers shift from whole-class instruction toward small group tutoring [Collins, 1991]. These changes occur because the technology takes over some of the traditional "information presenter" role of teachers, allowing teachers to interact in new and more effective ways with their students. Collins also indicates that the role of the student changes. Students become more engaged, learn at their own rates, and become collaborative as opposed to competitive.

Method

TESSI's TEI Professional Development Program is based upon the premise that, in addition to basic computer skills, teachers need meaningful exemplars of how technology can be used to enhance teaching and learning. One-day workshops are typically not effective in promoting enduring changes in teaching practice. Multi-day summer institutes may be more effective but they tend to be expensive to run and serve only a small percentage of teachers. Neither format provides the ongoing professional development opportunities and support for teachers that [Fullan, 1991] identifies as necessary for successful school-based innovations, nor the opportunity for practicing new skills in the classroom and reflecting on the results. The TEI Professional Development Program is based upon an alternate training model - that of a stand alone, interactive, multimedia program designed by teachers for teachers.

TESSI's TEI Professional Development Program is based primarily upon the experience TESSI teachers have had implementing TEI into Physics 11 and 12, and helping other teachers to implement TEI strategies. The Program draws upon an established research base, extensive teacher experience and documented results to generate an effective means of assisting teachers in negotiating the complexities associated with learning to implement TEI. The CD-ROM based program was developed using Authorware™ Professional on a Macintosh 8500 computer for both Macintosh and Windows platforms. Video segments include professionally recorded footage prepared for a province-wide video conference by British Columbia's Open Learning Agency. The CD-ROM format was selected to offer "just-in-time" practical knowledge when and where it is needed.

Incorporating text, sound, digitized images and video, the TEI Professional Development Program features:

- teachers describing and illustrating the structure and operation of a TEI classroom using both still images and video clips of TESSI classrooms.
- teachers introducing and providing exemplars of teaching and learning strategies that are effective in TEI classrooms.
- teacher and student perspectives on teaching and learning in a technology enhanced science classroom including their views on their roles.
- interviews with students, teachers and administrators about the essential outcomes of implementing TEI.
- teacher responses to frequently asked questions about TEI.
- lists, discussions and demonstrations of basic equipment and software.
- software tutorials.
- hard to locate technical information about setting up and maintaining a computer-integrated classroom.
- a teacher annotated bibliography of articles related to TEI implementation and research.

Educational Significance of the TEI Professional Development Program

The TEI Professional Development Program can be expected to have a significant impact on the further development of educational practice because it so directly addresses an essential educational need - training in the effective use of technology in the classroom for teachers, by teachers. The program promises to deliver inservice and preservice TEI training in an efficient, functional and cost-effective manner. The final program can be made available to individual teachers either as a CD-ROM or, eventually, on-line.

Hypertext Sexual Harassment Web Page

Nancy Wyatt
Department of Speech Communication
Delaware County Campus, Penn State University
Unites States of America
njw@psu.edu

Douglas Harvey
Instructional Systems
Penn State University
United States of America
dmh197@psu.edu

Abstract: This paper describes a hypertext web page on sexual harassment designed as one component of a gender and communication class at the Delaware County Campus of Penn State University. We explain the rationale for the choice of hypertext and describe how we designed and used the program. Finally, we evaluate the use of hypertext as a classroom pedagogy and provide suggestions for improvement. The web page address is www.de.psu.edu/harass/intro.htm.

Rationale for Using Hypertext

Sexual harassment is a very complex issue. Scholars, legal experts, and ordinary people struggle to define and characterize sexual harassment and to devise ways of preventing or dealing with the problem. Teaching about sexual harassment is also complex. No single pedagogy can provide a comprehensive treatment of sexual harassment. Group discussion allows for exploration of a variety of perspectives in an interactive forum, but good group discussion must be based on some shared understanding of theoretical concepts. Traditionally, these concepts have been introduced to students in lectures or reading assignments. Both lectures and text share the problem that ideas must be presented sequentially, making it difficult for listeners/readers to connect ideas from different sections of the lecture or of the book. Furthermore, it is difficult to convey effectively the complex emotional and psychological aspects of sexual harassment in linear texts. Finally, both lecture and text privilege the "voice" of the instructor as the expert instead of empowering the students to learn from their own experiences and to connect classroom learning to their professional and personal lives.

Hypertext can provide theoretical concepts, differing perspectives, and case studies on which to base group discussion of sexual harassment issues. Hypertext "decenters" the text and allows readers to structure the material in ways that make sense to them. Hypertext can provide links to external websites, situating the information in a wider context of "real life" experience.

Design and Use of the Hypertext Sexual Harassment Web Page

We set the following learning goals for students:

- to define sexual harassment
- to recognize behaviors that may constitute sexual harassment
- to know their legal rights and appropriate procedures if they are harassed
- to avoid acting in ways that might be interpreted as sexual harassment
- to explain sexual harassment to other people.

We collaborated with the Affirmative Action Office of Penn State University in designing the hypertext web page. We envisioned a program that would provide both legal and theoretical analyses of sexual harassment, supplemented by case studies and connections with other web pages and suggested reading. We also wanted

BEST COPY AVAILABLE

students to become familiar with Penn State's procedures for dealing with sexual harassment. The web page was organized into these six areas of information:

- Legal Definitions
- Theory and Analysis
- Cases
- Related Web Sites
- Bibliography
- Penn State Policies and Procedures

Students could begin in any one of these areas and follow links to move easily from one section to another. Students kept a log of their responses to the web pages as they worked their way through these six areas. We found that they did indeed take individualized paths through the material. The logs also revealed a wide variety of responses to and interpretations of the material.

Evaluation of Hypertext as Pedagogy

In designing the web page we worked closely with colleagues within and outside Penn State to locate appropriate resources and to create a web page responsive to the needs of a readership wider than the class itself. Such consultation is rarely called for when we rely on lecture as a primary pedagogy. The ability and necessity to link different aspects of the material through both logical and psychological connections was challenging, as we attempted to represent the complexity of the issues associated with sexual harassment. Designing the links among documents required us to keep in mind the needs and interests of our potential readers to anticipate the ways in which they might structure their reading. In that sense, the act of writing in hypertext established a stronger sense of connection with a wider set of potential readers than has the act of writing lectures or papers. We developed a much deeper understanding of sexual harassment and the multidisciplinary complexity of this topic than we might otherwise have done with a traditional pedagogy.

The logs kept by students as they read through the web page revealed that they forged a variety of paths through the material and developed differing perspectives on the material. We believe that links to web sites with related information provided a context in which the academic assignment clearly related to problems and programs in the larger world. Proponents claim that multiple paths through a hypertext empower students to read creatively, but we note that these multiple paths may also allow readers to avoid engaging perspectives different from their own to a greater degree than with a traditional text. Students reported that they enjoyed this assignment. The question of whether or not students developed an increased understanding and appreciation for the complexity of sexual harassment remains to be determined.

Writing in hypertext necessitated careful attention to the appearance of the text on the page, because the appearance of text on a computer screen is crucial to its success. We enjoyed designing beautiful pages, a reward unavailable in writing lectures or papers. In fact, most of the many positive responses to our web page have been editorial and not substantive. To the extent that browsing web pages partakes of entertainment and not of serious academic pursuit, use of this pedagogy may be problematic.

Future Uses of Hypertext as Pedagogy

Since we found the process of writing hypertext to be so fruitful, in the future we will incorporate student involvement in the design and production of the web page. Students will gather information from a variety of perspectives for inclusion in the web page; in this way they will be unable to avoid dealing with the controversial issues implicit in the topic. When students themselves must design the links among the document in the web page as well as the links to other web sites, they should develop a more complex understanding of the issues implicit in the topic. We also hope that this process will help students begin to understand the basic communicative processes that are involved in sharing information. We hope that students will learn to think carefully about the potential users of a web page and understand the psychological as well as the logical processes necessary to share information.

A Computer-Assisted Multimedia Language Testing Program: Chinese Computerized Adaptive Listening Test

Zizi Zhang
Media Resource Center
Randolph-Macon College
U.S.A.
zzhang@rmc.edu

Abstract: The Chinese Computerized Adaptive Listening Test (CCALT) is designed for testing Chinese listening proficiency. The target audience include the high school and college students who study Chinese as a second language. In this project, the computer is used to estimate the student's knowledge level, generate test items, present the item in the context, and record the testing data. The current item bank consists of over 350 items, and about one-third have been tested on 60 target students. Re-calibration of the items was done based on the testing results. The results also indicated that the CCALT tends to enhance the student's motivation and reduce test anxiety.

Computer and Foreign Language Instruction

To be proficient in a foreign language means to use the language in contexts and carry functions in the target culture [Omaggio, 1986]. Therefore, to present the language in authentic culture and contexts is critical in foreign language instruction. Video discs and CD-ROM's are ideal for this purpose. They can provide dynamics (motion pictures) and play high-fidelity still frames and audio. They are also more flexible in terms of providing fast random access to specific video segments [Altman, 1989]. Controlled by a computer, video disc and CD-ROM programs are more interactive than linear videos and other traditional media.

Many commercial computer-assisted language materials include exercises and tests, however, the format and items of these tests are less formal than computer-assisted language testing (CALT). In CALT, the computer is not only used to elicit and assess a student's language performance, it also offers stimuli and realistic contexts. The CALT can produce interactive, tailored tests where the test adaptive itself to the student's knowledge level [Noijons, 1994].

Computerized Adaptive Testing

Computers have been used for item generation and scoring objective tests. Modern research focuses more on computers' capability of interacting with the student. They can register the time the student spent on the item and the route of the student's through the test, estimate the student's level and select appropriate items. This feature is highly related to adaptive testing. A computerized adaptive test usually works this way: the computer first assesses the student's knowledge by giving a preliminary test which leads to an estimate of his or her level, then it searches the database for an item at the level and administers it. If the student responds correctly, the system adjusts its estimate upward. If his or her response is incorrect, the system adjusts its estimate downward [Alessi & Trollip, 1991]. It will eventually stop administering items when the level of the student is identified and the estimate becomes reliable.

The Chinese Computerized Adaptive Listening Test (CCALT)

In light of the research findings on computerized adaptive testing and the use of computer-assisted programs in foreign language instruction, I and my colleague began to develop the Chinese Computerized Adaptive Listening Test in 1994. The target students are the high school students and college students in the United States. who study Chinese as a second language. Currently the item bank consists more than 350 items. The items were inter-rated by Chinese listening test experts based on the ACTFL (American Council on the Teaching of Foreign Languages) Guidelines on listening proficiency [ACTFL Guidelines, 1987].

The test begins with a page collecting demographic data (the student's name and ID, and years of studying Chinese). Then a preliminary test is administered to obtain an estimate of the student's proficiency level. Based on the estimate, the computer routes the student to the appropriate item level and administers a question to him or her. The system then administers another item at the level or moves downward or upward depending on the student's response. The test stops when the student's proficiency level is identified. Data including time on each item, time on the test, and the student's answers are recorded.

Each item is presented through a movie clip (dialog/speech accompanied by dynamics) or a sound clip (dialog/speech) accompanied by a picture. A multiple-choice question with four options is displayed on the computer monitor after the audio finishes playing. The student clicks on an option to answer the question, then the computer takes him or her to the next item.

About one-third of the items belonging to the Novice Low through Advance levels were tested on 60 target students. A preliminary study of the online data and the students' responses to the questionnaire revealed that the correlation between the student's performance in the CCALT and in a traditional listening proficiency test is relatively high. The computer-assisted multimedia format made students less nervous than the traditional paper-and-pencil tests. Some students commented that the contexts / visual cues helped them understand more of the content, and made more sense than traditional test. The study was used to re-calibrate the items. Some items were moved to a different level, and some questions were re-written.

Technical and testing issues need to be addressed in the next stage of the development of the CCALT. Specifically, we will work on these aspects: First, the most challenging tasks are calibration of the current items and reliability study of the test. Each item will be exposed to one hundred targeted students. The results will be used for psychometric calculations (difficulty indices) and adjusting the algorithms. Further study will investigate the correlation between the CCALT and traditional proficiency listening test. Secondly, the sound embedded in the movie is not as high quality as the sound played with a picture, because the compressed movie occasionally produces frame drop-outs when being played back. Some movie clips will be re-compressed with newer technology. Thirdly, an effective delivering method needs to identified. Should it be delivered from a CD-ROM or through LAN? What are trade-offs of using either method?

POSTER/DEMONSTRATIONS

Strategies Instruction: Mathematics Problem Solving using Computer Based Instruction

Doehee Ahn*
Robert F. Mulcahy**
Department of Educational Psychology
University of Alberta
Canada

E.mail*: dahn@gpu.srv.ualberta.ca
E.mail**: bob_mulcahy@ualberta.ca

Enhancing students' problem solving skills in mathematics has been a major concern of educators over the years. This might be resolved by combining cognitive and metacognitive strategies instruction. Some researchers suggested that computers can be used to teach problem solving skills explicitly and improve learning processes. This is, because computers provide students with a friendly means which presents computer graphics, movement of figures, and immediate feedback. Combining computer based instruction with structured teaching can be a powerful supplement to classroom instruction. Therefore, a Computer Based Instruction (CBI) program was developed to explore the potential of using this means to teach grade six students problem solving skills in mathematics problem solving. A general strategy, SPIDER was developed and embedded to facilitate students' mathematics problem solving performance by cueing them in the major components in mathematics problem solving.

A Multimedia Application to Teach First Year College Calculus

Silvia Aiassa, C.I.S.D.A., Politecnico di Torino, Italy, Aiassa@araxp.polito.it

Evandro Costa, C.I.S.D.A., Politecnico di Torino, Italy, Costa@araxp.polito.it

Manfredo Montagnana, Dip. Matematica, Politecnico di Torino, Montagnana@araxp.polito.it

This multimedia contains mathematical subjects of a first year Calculus course in Engineering.

Subjects correspond to the chapters of a book: foundations, real numbers, numerical sequences, limits, differential calculus, integral calculus, ordinary differential equations.

Each subject is organised in four **Areas**: Theory, Practice, Investigation, Indexes.

The Theory area contains: definitions, theorems, exam questions. Similarly, in the Practice area, users meet: examples, exercises, exam questions; while in the Investigation area they find epistemological unfoldings and historical investigations. The Index area gives students a general view of all algorithms and numerical tables.

A specific mathematical software allows users to answer questions and compare their results with installed solutions.

The Investigation area shall be completed for the final edition of Mediamath, expected next year.

Mediamath is intended for an MS-WINDOWS based Pc. The final product shall be installed in both Stand-alone and Client-Server versions; it will be masterized on CD-ROM.

Knowledge-Based Medical Training Systems

N.Ampilova, Math.&Mech.Faculty, St.Petersburg State University, Russia, nba@niimm.spb.su

E.Gurevich, Inform Engineering Ltd, St.Petersburg, Russia

E.Strakhovich, Institute for Information and Automatization of
Russian Academy of Sciences, St.Petersburg, Russia

Two based on the expert knowledge training systems are described. The first of them is associated with investigations of histological preparations, the second one is assigned to. the electrophysiology area and designated to determine evoked potentials on electroencephalograms. When exploring the preparates, the construction of *associative image series* [see Granovskaya and Bereznaya, 91] was used as the main training method. By this series we mean the sequence of images, each of them is the coded input image and depicts some information sign. Solving our problem we coded this sign by color according to some scale. So, we impose the input preparation image and two coded pictures together. Simultaneous presentation of all images allows to originate the associative series with desired directionality. Computer processing of EP has traditionally followed two basic methods: using Fourier transform and the structural approach to curve processing [see Kulanchev and Kaplan, 94]. We have developed the method [see Ampilova and Strakhovich &amp; Ampilova, Grachev and Strakhovich, 95], based on using by expert of revealable features. The models were implemented on IBM PC. As input data we used the cipher signals and images, obtained at output of traditional medical equipment.

Using Multimedia for Promotional Purposes in Education: A Multimedia Presentation about the Division of Technology

Patricia Ryaby Backer
Division of Technology
San Jose State University
1 Washington Square
San Jose, CA, 95192-0061
pbacker@sjsuvm1.sjsu.edu

Brochures, flyers and catalogs have been used as traditional promotional and informational materials for departments and universities. This presentation demonstrates a new form of promotion—the use of a multimedia CD-ROM that describes the programs housed in the Division of Technology at San Jose State University. This multimedia was developed by a team of students in conjunction with a faculty member and is used to present information about the undergraduate majors in the department. The multimedia development has undergone two revisions and is presently being beta-tested by the Division.

Our Involvement with 400 Multimedia Projects: Structuring the Process for Effective Learning

William G. W. Barnes, Choate Rosemary Hall, Wallingford, CT USA wbarnes@Choate.edu
Thomas S. Foster, Choate Rosemary Hall, Wallingford, CT USA tfoster@Choate.edu

The results of three years of multimedia assignments given to high school students suggest a high level of technical knowhow among all group members is less important than a full understanding of the process under which the project will be carried out by the team.

Specifically, students made strong use of templates for gaining control of a project. Templates in this study included teacher-prepared documents with 15 screens, embedded navigational links, and sample texts. The templates acted as an extension of the teacher, guiding the students into the use of a multimedia authoring program. For novices, the bulk of the work remained typing or cutting and pasting from a text document because the template could be relied on for its use of color, position of buttons, serial links, and placement of text on each screen. For experienced users, the templates could be readily modified into a more dynamic document with complex links and menu structures. Throughout this work, the teachers pushed the idea that if the writing were terrible, the overall project would not succeed as flashy media could not compensate for weak research and poorly developed ideas.

Second, students worked best when a team captain from each group was trained extensively in each technical skill and, in turn, taught the respective members of their teams the same skills. Groups functioned well when a division of labor took place among its members with responsibilities for sound production, scanning, design, final editing and beta testing. Most team members learned all of these skills.

Last, the teachers who set aside sufficient blocks of class time were more satisfied with the outcomes of the projects. A variety of techniques emerged to deal with procrastination and divisive team structure.

Preview of a Multimedia Textbook for CS1:
The Universal Machine:
A Multimedia Introduction to Computing

Glenn D. Blank, EECS Department, Lehigh University, USA, gdb0@lehigh.edu

Robert F. Barnes, EECS Department, Lehigh University, USA, rfb1@lehigh.edu

Ironically, in current computer science courses, the computer is seldom used as a dynamic instructional tool. Although many texts now include a floppy disk containing problems or programs, the usual work disk barely scratches the surface of what a computer can do to present multimedia instruction. Multimedia can far exceed the capability of a textbook, using a personal computer to present materials that are beyond the scope of text. Moreover, hyperlinks and indices facilitate non-linear exploration of concepts, encouraging students to learn on their own. In addition, multimedia can provide a more congenial environment for those students whose learning styles lean more to the concrete, participative approach, rather than the typically more abstract, reflexive approach of most programming courses. We believe the substantial multimedia component of our forthcoming CS1 textbook--which we demonstrate--will offer a number of novel educational advantages, both to teacher ans student.

ORWelt - A Hypermedia Learning Environment for Operations Research

Astrid Blumstengel
Decision Support & ORLab (DS&ORLab)
Department of Business Administration
University of Paderborn, Germany
blumstengel@uni-paderborn.de

ORWelt is a modular hypermedia system supporting business students in learning Operations Research (OR). The ORWelt project was started in response to the significant need for educational software expressed by OR-teachers and students.

A core component managing navigation and administration was developed by researchers at the DS&ORLab while major subject and test modules were developed by students themselves.

All components are hyperlinked and provide access to a glossary. Navigational tools include a graphical browser for structural orientation and direct access to components, user-defined bookmarks, annotations and full-text-search capabilities. Guided tours can be defined according to the needs of the individual user.

Small simulations and professional optimization software were included to allow students to explore the results of changes of parameters on the solution of presented problems.

Our current work focuses on including complex case studies with links to the methodical components to provide an alternative problem-oriented approach to the material.

Learning strategic management with NetStrat, a distributed business simulation

Jacqueline Bourdeau, Department of Education, Universite du Quebec a Chicoutimi, CANADA,
jbourdea@uqac.uquebec.ca
&
Laura Winer, Faculty of Education, Universite de Montreal, CANADA, winerl@ere.UMontreal.ca

As part of a project on instructional design for collaborative distance learning for the workplace, observations have been made on collaborative learning aspects of the learning of decision-making in strategic management supported by a computer-based business simulation. Teams are formed and given the task of making a series of decisions in a competitive business environment. After each round, results are computed and given to the students to guide their decision-making process. A Web-based distributed simulation called NetStrat has been developed to support telelearning situations, and will be demonstrated with on-line instructor and team.

Does Internet Communication Affect Performance? Some Results for Distance Learning Introductory Computing Students

Linda Carswell
CIER (Centre for Informatics Education Research)
The Open University
Faculty of Mathematics & Computing
Milton Keynes, England, MK7 6AA, UK
L.Carswell@open.ac.uk
Telephone: +44 (1908) 65-2696
Fax: +44 (1908) 65-2140

Abstract

The use of the Internet is a common theme in current educational technology research. However, hype does not augment learning, and new technology alone does not promise improvement. The question is does Internet presentation alone affect learning outcomes? This study examines two groups of distance learning students on a single course, (introductory computing) using the same learning materials, but with different means of communication. One group consists of conventional distance learning students who communicate with their instructors via telephone and written correspondence, while the other group communicates electronically via the Internet (this includes electronic tutorials and electronic assignment submission). Attitudes and average assignment grade are compared for each group to assess the impact of the Internet. The results indicate there is no significant difference in average assignment grade between groups. In this study the Internet is not found to have any significant effect on learning outcomes, as determined by average assignment grade.

Designing and Developing an Interactive Multimedia, Learn-by-Doing Simulation

Bryan Carter, Designer
The Performance-Based Learning Team
NCR Worldwide Services Organization Development, USA
Email: bryan.carter@daytonoh.ncr.com

Tim Underwood, Learning Architect
The Performance-Based Learning Team
NCR Worldwide Services Organization Development, USA
Email: tim.underwood@daytonoh.ncr.com

The Digital Communication Fault Analysis simulation is being used to serve the training needs of over 2000 NCR customer engineers (CEs). These engineers are responsible for traveling to customer sites where they install, diagnose, and repair equipment. This learn-by-doing simulation is distributed on CD-ROM along with "real world" documents that the CEs actually use in the field.

The virtual environment created in the simulation very closely mimics the real world environment of a CE. The learner begins in the District Office where the territory manager discusses the overall goal for a major network upgrade project. To complete the program the learner must successfully install and repair network equipment at twelve customer sites. Many support resources are provided to facilitate learning, including an electronic performance support system, video tips from experts, and mini-tutorial sequences.

To create this learning simulation an iterative, user-centered design and development process was followed.

MAESTRO: The Writing Process Tutor

Melinda Crevoisier
Command Technologies, Inc.
USAF Armstrong Laboratory / HRTI
Brooks AFB, Texas USA
E-mail: crevoisier@cobra.brooks.af.mil

Dr. Kurt Rowley
Command Technologies, Inc.
USAF Armstrong Laboratory / HRTI
Brooks AFB, Texas USA
E-mail: rowleyk@cobra.brooks.af.mil

MAESTRO is an adaptive writing process tutor for high school level English instruction. It was developed for the Fundamental Skills Training Project, a research project with the goal of transferring advanced, adaptive training technologies to the public education sector. *MAESTRO* is a process-oriented automated tutor that follows a cognitive apprenticeship instructional strategy in the semantic domain of writing. The tutor is being tested during the 1996-1997 school year at 24 high schools and middle schools in five U.S. states: Texas, New Mexico, Ohio, New York and Pennsylvania. This demonstration will include: (1) a demonstration of all levels of the tutor; (2) an illustration of a typical session for a student using the tutor, including adaptive advice, tailored instructional modules, and real-life writing assignments of video, graphic images and readings that depict interesting and probable writing situations; and (3) an opportunity for hands-on experimentation with the tutor.

Developing Multimedia Programming for Upper-level Foreign Language Courses (Literature and Civilization)

Dr. Rick DCamp, German
Director Foreign Language Laboratory
DFLL, University of Wisconsin Oshkosh
800 Algoma Blvd., Oshkosh, WI 54901
E-mail: dcamp@vaxa.cis.uwosh.edu
Phones: (414) 424-0910/4017/4004

Dr. Carole Byrd, Spanish
Coordinator Spanish Language Program
DFLL, University of Wisconisin Oshkosh
800 Algoma Blvd., Oshkosh, WI 54901
E-mail: byrd@vaxa.cis.uwosh.edu
Phones: (414) 424-0909/4017/4004

Because most multimedia computer assisted programs for Foreign Lanugages are targeted towards lower level language learning, first and second year, we are demonstrating two multimedia programs that are designed to meet the pedagogical needs of upper level literature and culture classics in German; Spanish. The Spanish program presents an overview of Nineteenth Century Latin American Literature and Culture employing segments of the film *Camila* based on a biography written during General Rosas' Federalist regime in Argentina and student made videos. The German program will focus on the works of Hildegard von Bingen, finally treating the trial in 1148 of Hildegard, a highly educated, medieval, mystic nun by the Archbishop of Mainz.

These projects have been developed on a Power Macintosh 7500/100 PowerPC using HyperCard 2.3, Quicktime Tools for HyperCard, Apple Video Player 1.3.1, MoviePlayer 2.5, MovieCleaner Lite 1.2, BigSound version 1, an Apple Color I Scanner, HyperCard Color Tools, Microsoft Word 6.0.1, and a CDR-CD burner. We felt the Power macintosh is advantageous because it is a multimedia machine with most of the needed technology built-in. The HyperCard program is simple and inexpensive to use, and compatible with the Power Macintosh. Both sound and video movies were created with the MoviePlayer program. Sound movies were created initially using BigSound. Using MoviePlayer, BigSound files were later converted as QuickTime movies. Sound files were installed into HyperCard "as is." Videos were recorded using the Apple Video Player, and compressed using MovieCleaner Lite to save memory. Images used in these programs were scanned on the Apple Color I Scanner, saved as PICT files, and placed in the HyperCard stack using the HyperCard Color Tools. When our programs were satisfactorily completed, they were saved on a compact disc using a CDR CD burner.

"*CyberRecess*^{TM} - The Development Of A Dynamic, Contextual Application For Enhancing Learning Through User-Driven Authoring Using The Internet."

Manuel da Costa, Development Manager, Learning Services
MediaLinx Interactive, Toronto, Canada
E-mail: mdacosta@medialinx.ca

Vikki Saunders, Project Manager, Learning Services
MediaLinx Interactive, Toronto, Canada
E-mail: vsaunders@medialinx.ca

CyberRecess^{TM} is a multimedia educational application, designed for children from kindergarten to grade 12 (K-12), in which the setting of a particular context is used as the basis for the creation of dynamic, user-driven content. Based on a learner-centred model and constructivist principles, *CyberRecess*^{TM} empowers and challenges the student to engage in active learning. It is an application with a key difference! *The content is entirely generated by users for consumption by their peers.* Students effectively become publishers and, through communication with "contextual editors", they can shape the design and development of future contexts so that relevance of the application is assured from a user point of view.

CyberRecess^{TM} has six basic sections based on Science, Mathematics, English, Art, Humor and the "*Wired Goose Chase*"- a section that allows for the development of online research and navigational skills. Any student with Internet access can participate in *CyberRecess*^{TM}. Submissions are screened and qualified by a team of editors and selected entries are posted. The experience is truly empowering as every child is presented with the possibility of authoring, publishing and sharing their work and experiences with other children elsewhere.

Using Educational Technology in Discovery Learning

Cynthia L. David and Debra Dlugolenski
Augusta Technical Institute
Augusta, Georgia USA
cdavid@augusta.tec.ga.us
ddlugole@augusta.tec.ga.us

Discovery learning is a constructivist method of education in which students work in collaborative teams to solve problems. At Augusta Technical Institute we have developed a model for discovery learning in the community college environment. Our model consists of 3 major foci: communication, information utilization, and collaboration. Central to this model of discovery learning is the appropriate use of educational technology to improve the richness of information available to the student and to enhance the problem-solving process via computer-based simulation and asynchronous communication.

Communication includes e-mail and web-based conferencing. Information utilization emphasizes on-line search strategies and ways to analyze the resultant data. At the end of each problem, teams share their problem-solving strategies with the entire class. The details of a biology curriculum unit will be presented. This problem-based scenario involves an inherited genetic disease and incorporates elements of genetics, cell biology, pathophysiology, and ethics.

The Information Superhighway and Telecentres in Australia

A F Dean
Information and Communication Technology Department
University of Wollongong, Australia
tony_dean@uow.edu.au

Abstract: This paper explores the inception, development and ongoing battles of telecentres (telecottages) in the Australian context. Australia, the island continent, is among the most urbanised of countries. Its vast geography and habitation patterns present fundamental problems for policy makers in the telecommunications field. The myriad recent developments in telecommunications, computing, broadcasting and publishing industries present technological solutions to some of the perennial problems faced in the rural and remote areas. Telecentres are examined with a view to judging their potential to service the populations in these regions and to see if the information superhighway holds any allure in such developments. The place and role of education in the telecentres' operations is investigated together with an exploration of the pressures that the telecentres are under in their efforts to remain viable.

---

iDEANet - An Exploration of 'Poly-Media':- the Potential of Compressed Video Television in Distance Education.

A. F. Dean
Information And Communication Technology Department
University of Wollongong, Australia
tony_dean@uow.edu.au

This paper draws on path breaking experimental work conducted by the author which combines broadcast television with computing, and video and audio conferencing. The paper takes a 'what if' approach to show that this is a low-cost alternative for interactive distance education. The suggested configurations can be replete with high-technology aides or can be streamlined to suit the purpose of the educational endeavour and scaled back, where necessary, to match the existing information and communication infrastructure. The paper will draw on the original 'poly-media' configuration trial and the presentation, which is intended to be interactive and collaborative, will consider further hybrid application of the approach.

Testing by Doing: A Case Based Approach to Testing

José E. Díaz-Camacho
Instituto de Investigacion y Desarrollo Educativo
Universidad Autonoma de Baja California

and

Richard G. Feifer
Department of Education
United States International University

A computer assisted system for testing professional proficiency in psychology was built by using the cognitive principles of Intelligent Tutoring Systems design. This system combines the main advantages of the existing approaches for testing which are: written multiple-choice xaminations and oral panel examinations. Therefore, the system is aimed to be, capable of computer scoring, standardized, bias free, and ecologically valid. These goals are pursued by computerized psychological simulations where the psychologist may search for relevant information by asking simulated persons, to relate the intake information with the relevant diagnostic classification system, planning a treatment, and, evaluating the effect of the intended treatment on simulated prognoses.

MERIMNA: An Interactive Multimedia Learning Environment in Bookbinding for Mentally Handicapped People

Dobridis Thomas

Garofalakis John (garofala@cti.gr)

Panayiotaki Angelliki

Sirmakessis Spiros (syrma@cti.gr)

Tsakalidis Athanasios (tsak@cti.gr)

Tzimas Giannis (tzimas@ceid.upatras.gr)

Department of Computer Engineering and Informatics - University of Patras, 26500 Patras, Greece
and
Computer Technology Institute, P.O. Box 1122 , 26110 Patras, Greece

In this work we present a fully interactive computer based training tool in bookbinding for mentally handicapped people. MERIMNA is an easy to use multimedia-based system providing training over a LAN to mentally handicapped people. The system contains several training courses, depending on the level of the mental disability of each trainee. The courses have been designed for disabled from the age of sixteen to thirty. They aim in providing vocational training for their integration in the normal way of life. The teacher is able to keep track of each student's performance and to adjust the lessons series according to his/her improvement.

A Process Oriented Evaluation Model for the Learning Enhancement Envelope (LEE) Projects

Mike Dobson
Program for Advanced Learning Systems
University of Calgary, Canada
mdobson@acs.ucalgary.ca

Janet McCracken
Advanced Computing Business Unit
Alberta Research Council, Calgary, Canada
janet@arc.ab.ca

Brian Gaines
Faculty of Graduate Studies
University of Calgary, Canada
gaines@acs.ucalgary.ca

Bill Hunter
Faculty of Education
University of Calgary, Canada
hunter@acs.ucalgary.ca

The Advanced Education and Career Development ministry of Alberta allocated a total of $30 million over three years to be distributed through a Learning Enhancement Envelope to higher education institutions for the purpose of expanding opportunity, improving learning and increasing productivity. The Lessons Learned (LL) project at the University of Calgary is a mechanism for communicating the challenges, approaches, and results of the Learning Enhancement Envelope (LEE) projects within the university, to other Alberta higher education institutions and beyond. Projects currently under development encompass a variety of disciplines (for example social work, medicine, art, history) and consider a wide range of technologies to support learning and teaching, including web-based course delivery, videoconferencing, CD-ROM development, simulations, and CAL. A repository of information designed for interactive case based *lessons learned* will be integrated with an automated management system. The design for this system is based on the learning and instruction development sub—committee toolbox also known as LIDS—TB (Gaines, 1997), and draws on work in interactive case based approaches to instruction (Dobson, 1997). This session presents a work-in-progress demonstration/discussion of the application of a process oriented evaluation model used by the LEE project teams. The evaluation model is based on the idea that evaluation is an integral part of the design—development—implementation—evaluation cycle. Emphasis is placed on use of direct interviewing and observations of students in order to gain insight into the qualitative ways in which students are thinking about materials they are learning as well as the learning approaches they are taking in approaching the materials.

Creating Multimedia Environments to Support Collaborative Learning

Dieter Engbring, Ursula Schwolle
Heinz Nixdorf Institut
Universität-GH Paderborn, Fürstenallee 11, D-33102 Paderborn, Germany
E-Mail: {didier | ulla}@uni-paderborn.de

Abstract

Learning is an inherently social process. However, the use of multimedia is quite often refined to support individual learning processes only. As a consequence multimedia ist often regarded as a means to replace social learning settings by individual learning activities or tele-learning. In our research group "Computers and Society", we follow the opposite approach. We have created a learning supportive infrastructure to study how best social learning processes can be supported by the use of multimedia regardless whether it is tutorial, seminar, lectures or individual learning. We distinguish four different areas where support of collaborative and social learning processes can take place. This paper describes the typical problems which arise in these four areas and discusses our ways to solve this problems.

Cooperating Virtually about Virtuality: Promoting interdisciplinary Efforts

Enrique D. Espinozsa, Isabel N. Vallejo, Sandra Ramos,
Patricia Escamilla & Anabel S. Gutierrez, ITESM-CCM
eespinos@campus.ccm.itesm.mx

We will present our proposal software for an interactive media which supports interdisciplinary-based Computer Based Education (CBE). Given our fast-paced workstyle, it becomes hard, if not impossible, to negotiate continuous, long lasting design meetings with several experts. These experts are faculty from diverse schools in our campus who contribute to the virtualization of a course. It has been proposed that the Internet become, using *Collaboratories*, a preferred means for bringing together people into the course redesign process. We have chosen to use the Java technology as a tool for the implementation of such a Collaboratory. Our objective is to allow a flexible and distributed instructional design, which we eventually plan to convert into a CAVICE (Computed Aided and Virtual Instructional Course Engineering) scenario. The WWW is becoming a widespread tool within our academic community. We intend to contribute with a method for educational collaboration via the Internet.

Navigational Patterns in Interactive Multimedia

Sue Fenley,
Institute of Educational Technology,
Open University,
Walton Hall,
Milton Keynes MK7 6AA
e.mail s.i.fenley@open.ac.uk

Abstract :

The navigational patterns research paper commences with a critical review of work by researchers, interrogating the types of navigation patterns that they have identified, usually in hypertext or more rarely in multimedia.

After investigating these, some empirical work has been completed, allowing a series of navigational patterns for multimedia to be developed, which are both more comprehensive and recognisable from their present usage and for future work. These patterns are then tested further empirically, where the users navigational strategies are analysed in terms of these classifications, these are then represented with a description of each pattern, and are then related to those of other researchers.

The poster shows navigation patterns recognised (Chart 1) and my navigational patterns with descriptions. The full research paper critically analyses these and relates them to the empirical work before producing some conclusions on how these navigational patterns are actually being used in interactive multimedia.

Demonstration Details

Increasingly, K-12 teachers and students are surfing the Internet in search of images, information, and ideas that support and extend their educational objectives. Unfortunately, what they are finding is that the resources they seek are often scattered across hundreds of databases, home pages, and documents. Furthermore, most teachers and students have no clear idea of how to incorporate Internet-based resources into normal classroom teaching and learning. Prototype K-12 classroom activities are needed that model the use of on-line images, information, and computational resources. In addition, these prototypes should model the integration of science, mathematics, and technology in contexts meaningful to K-12 students. In response to this need, the Network Montana Project (NMP) is collaborating with teams of teachers, scientists, and mathematicians to develop Internet-based, K-12 classroom activities and related distance learning courses that integrate mathematics, science, and technology in the context of meaningful issues.

Designing Virtual Practicums for Pre-service Teachers: Three Project Iterations

A. Margaret Fryatt,
Nechako Electronic Busing Program TM
School District #91 (Nechako-Lakes),
Vanderhoof, British Columbia, Canada.
mfryatt@mail.sd56.bc.ca

David A. Gregg,
Nechako Electronic Busing Program TM
School District #91 (Nechako-Lakes),
Vanderhoof, British Columbia, Canada.
dgregg@mail.sd56.bc.ca

Abstract: This paper reviews the development of three Virtual Practicums for pre-service teachers over a 12 month period. The first iteration of the project involved matching more than 20 pre-service teachers at Massey University (Palmerston North, New Zealand) with 40 students drawn from the Nechako Electronic Busing Program TM and Sinkutview Elementary School (Vanderhoof, B.C.). This electronic project was delivered over a period of six weeks. A second pilot project explored the potential of Virtual Practicums connecting pre-service teachers from the University of Calgary with On-line Teachers from the Nechako Electronic Busing Program for a six week on-line teaching /learning experience with E-Bus families. Recommendations arising from this experience were incorporated into the Third Project, a full practicum offered during the 1997 winter term, connecting student teachers at the University of Calgary with On-Line teachers from the Nechako Electronic Busing Program TM .

THE RISE PLATFORM: SUPPORTING SOCIAL INTERACTIONS FOR ON-LINE INTERNET COLLABORATIVE TASKS

Michael Gardner
Human Factors unit, BT Laboratories, Martlesham Heath, Ipswich, IP5 7RE, UK
Telephone +44 1473 647784, Fax +44 1473 637557,
Email: michael.gardner@bt-sys.bt.co.uk

RISE (Real-time Interactive Social Environment) is a generic platform developed as part of the Education & Training research programme at BT Laboratories. The first application of RISE is a World-Wide-Web (WWW) based system (called Merlin) developed in conjunction with Hull University, which incorporates an on-line English as a Foreign Language course, accessible from anywhere on the internet. It is the first of several Televersity applications that are being built using the RISE platform. This work is underpinned by a common learning framework developed by Terry Mayes at Glasgow Caledonian University. In particular it supports the view that dialogue is one of the keys to effective learning. Future educational systems must not only foster dialogue and be situated in meaningful tasks but also recognise that much of learning is a product of a social process resulting from learners interacting with each other.

Network - Based Learning and Future Educators

Boyka Gradinarova
Assistant Professor, Computer Science Department
Technical University of Varna
Bulgaria
e-mail: Boyka@tu-varna.bg

Abstract

Terms such as the Internet and broad band have replaced CD - Rom and multimedia as this year's buzzwords. But the growing interest in communication systems is more than just a passing fad: it will change fundamentally the way many people teach, learning, and access information.

The educational potential of communications is huge, but there is some concern that in the rush to embrace the technology, many important issues are either being forgotten or over looked. There is little ability or effort to organise, contextualize and develop coherent educational experiences.

Educators will need support to learn how to take advantage of - end drive - the technological evolution of the Global Network.

The aim of our research is define the best way of use a medium in a given situation.

Key words: Internet, University Education, Case Study

Internet Broadcasting in Distance Education

Joel Greenberg
Centre for Educational Software
Academic Computing Service
The Open University
United Kingdom
j.greenberg@open.ac.uk

The British Open University currently has some 47,000 students studying courses which require them to have access to a personal computer. Of these, around 23,000 have modems and an increasing number have machines with multimedia components. The main teaching media of the University continues to be print and this is complimented by television and radio broadcasting, audio and video cassettes and computer-based teaching materials. An increasing use is being made of network services such as computer mediated conferencing and the World Wide Web to replace face-to-face tuition and to provide distance learners with additional resources in their studies. Internet broadcasting offers another complimentary teaching media for the University and a number of projects have been carried out to explore its potential for distance education. Internet broadcasts which are intended mainly for university staff are a natural extension of the organisational use of electronic mail, computer mediated conferencing and the Internet. Broadcasts of this type can be particularly effective because participants tend to have access to more network bandwidth in their offices than at home and it is this application which is likely to be

Sport Nutrition - Educating Athletes Through Multimedia

Proper nutrition before, during and after competition is crucial to an athlete's success. Dietitians and nutritionists are the experts whom athletes consult; however, professional dietary advice is not always available when needed.

The Multimedia Sport Nutrition project examines teaching and learning models in the application of athletic nutrition. Traditionally, learning theories and instructional design practices have been developed which focus on a specific type of learner or method of learning. Classroom instruction is further bound by the teaching/learning style of the instructor.

One of the benefits of multimedia instruction is the ability to deliver instruction tailored to the learner's style, level of content knowledge and preferred mode of instruction. This project will examine the relationships between these factors and look at multiple presentation methods.

Development of Network based Shogi Learning Environment

Toshihiro Hayashi and Yukuo Hayashida

Department of Information Science, Saga University, Japan
{hayashi, hayasida}@is.saga-u.ac.jp

The information network has been researched as the effective and applicable technology. Many researches on educational system also attempt to extend the field of study from stand alone system to network based CAI system. As one of network based CAI systems, we are currently developing a network based learning environment called "NESSY" (NEtwork Shogi SYstem) for learning Shogi (Japanese Chess) game. NESSY supports a student to learn how to play Shogi game. NESSY provides plural learning modes for playing, watching and discussing Shogi game. The student can observe the progress of others' Shogi game in watching mode. S/he can also exchange views with others on Shogi game in discussion mode. S/he can learn Shogi through the above-mentioned experiences on NESSY.

Strategies and Assessment in Mathematics Teaching: Multimedia resources for math-education courses

Ms Jan Herrington,
Edith Cowan University, Pearson St, Churchlands, 6018, Western Australia

Dr Ron Oliver
Edith Cowan University, Bradford St, Mt Lawley, 6050, Western Australia.
email r.oliver @cowan.edu.au

It is commonly accepted that teachers teach the way they were taught and that innovation is difficult to achieve. Teacher education courses often involve tasks that require students to process knowledge that is unconnected to situations in which the new knowledge will be applied. Consequently, the knowledge and abilities that are learnt have little chance of transfer to real classroom situations. In an attempt to overcome this problem, the theoretical framework of *situated cognition* or *situated learning* has been used in this project to design some interactive multimedia resources that allow preservice teachers to become aware of different assessment and teaching strategies in mathematics education and how to apply them. The resources enable users to encounter the authentic use of a range of assessment and teaching strategies and to view their interpretations from multiple perspectives which include the teacher's decision-making processes, the child's thinking, expert opinion and written documentation.

USING COMPUTER GRAPHICS and ANIMATION to VISUALIZE COMPLEX PROGRAMMING CONCEPTS

Issac Herskowitz
Department of Academic Computing
Touro College, USA
<issach@touro.edu >

This paper describes the "C-book" software development project. C-book is a computer aided teaching tool (CAT) for instructors of the C programming language. The tool provides graphics and animation allowing the instructor to visualize complex lecture concepts. Related literature has shown that visualization is a highly effective pedagogical way of transmitting information, and C-book reflects in this area.

The Hyper Resourceful Syllabus and Its Contents

Susan C. Hines, Assistant Professor of English
Jessamine Cooke-Plagwitz, Instructor in German
Middle Georgia College

Instructors everywhere are beginning to appreciate the Internet. Indeed, they are not only going "online" in droves, but many of them are going positively "hyper." They are designing indispensable hypermedia and multimedia resources that deliver course readings, lectures and assignments to students -- wherever they may be -- at the "click of a mouse."

One can "stay current" in one's field through regular e-mail correspondence with friends and colleagues all over the world, while "going future" with the help of numerous generous academics. One can access the ongoing work of instructors who take the time to list their course syllabi at the World Lecture Hall, and there is a growing number of institutions developing online teaching centers as well as online or "Web assisted" courses.

Education will continue to be mediated by computers and other technologies. Instructors who have the skills to put their syllabi in cyberspace, to develop resourceful and interactive Web pages with scripting languages (such as Java or Perl) or multimedia programs (such as Authorware or Astound), have a real edge. Not only have they already rewarded their students, their colleagues, and their institutions with their hard work, but they have begun to prepare themselves for the future of education and their place in it.

A Windows-Based Automated Sports Carnival Management Tool

Selwyn Hope
David Calder
Curtin University Of Technology
GPO Box U 1987
Perth 6001
Western Australia
Contact Author email = calder@cs.curtin.edu.au

Sporting carnivals at schools require enormous amounts of time and effort to plan and run. An automated system would greatly reduce the workload and provide a simply modified and used system. A prototype automated system has been developed and is currently the subject of beta tests at certain West Australian school events.

An automated solution to carnival information management needs to address key areas such as time scheduling in order to reduce the planning and running stages of the carnival. This software tool attempts to help in three main areas of the entire process; planning the events, placing competitors into events, recording and tallying results. An automated solution has necessitated the construction of a competitor database.

The *Automated Sports Carnival* has been developed on an IBM Pentium 100 computer and will run under Windows 95. The project is undergoing feedback and review at the moment. However, it is hoped that a commercially viable product will be available in the near future.

Interactive CSCL System Based on Three-Dimensional Shared Space

Katsumi Hosoya, Akihisa Kawanobe, Susumu Kakuta, and Yasuhisa Kato

NTT Information and Communication Systems Laboratories
Nippon Telegraph and Telephone Corporation
9-11, Midori-Cho 3-Chome, Musashino-Shi, Tokyo 180 Japan
katsumi@isl.ntt.co.jp

We focus on three-dimensional computer graphics (3D-CG) and animation technology as a educational tool for Computer Supported Cooperative Learning (CSCL). Although some experiments using 3D-CG in educational fields have been reported, most of those systems are of the stand-alone or pre-downloading type. We have developed an interactive and cooperative educational system using 3D-CG, which consists of several clients used by students and a server managing the status of educational materials in a virtual classroom. Each 3D object is defined as a distributed object based on the CORBA[1] architecture to keep the status of educational objects in the virtual classroom consistent. The system allows several students in various locations to cooperatively manipulate any object in it and to create a new one. By interacting with the objects and each other, the students can intuitively learn about a wide range of phenomena.

[1] Common Object Request Broker Architecture defined by the Object Management Group.

Together on the Web

Cynthia J. Hutchinson, Gary Hyslop, Andrea J. Wachter
University of Central Florida
hutchins@pegasus.cc.ucf.edu

Collaboration among students and teachers created a Web site for Florida's Altamonte Elementary School. University of Central Florida students, whose teaching strategies class met on the elementary school's campus, teamed with small groups of elementary students, guiding the 19 Dream Teams through the development of their Web pages. The university students received instruction from the UCF Curriculum Materials librarian in using web-authoring software, Claris Home Page. A microcomputer applications class at Point Park College in Pittsburgh objectively critiqued the home pages, following a rubric developed by the UCF professor and librarian. The PPC students benefitted from the data communications aspect of the project. Three goals were realized: exposing preservice teachers to outside collaboration's benefits; sharing teaching and learning in technology projects; introducing university and elementary students to planning, designing, building and publishing home pages on the Internet.

Exploring integrated audio/text Internet presentations in an educational context.

Gloria Jacobs, Joni Falk, Bridget Mooney, Jack Lochhead, Brian Drayton, Jon Obuchowski.

TEECH is an electronic community that connects leaders in the field of teacher enhancement. Over 600 projects that involve teacher professional development are currently connected on this site http://teech.terc.edu/ This site incorporates a searchable database, active discussion groups, papers on various topics and a lecture format which includes RealAudio as well as graphics and overheads.

In the context of this large, quite diverse community of leaders in the field of professional developments, we have been experimenting with the use of Real Audio and assessing the value that is added by bringing sound to the very visual web. We have experimented with using this technology to bring "virtual lectures" and "virtual panels" to our community. This provides a shared experience for a large group of people who would not generally have access to the same lectures.

Our primary question is how can RealAudio most effectively be combined with existing resources? What value does voice add? How can it be most effectively presented?

We have experimented with several modes, and we present the results of a comparison of them with a focus group of teacher enhancement professionals. We have used two kinds of material: presentations to conferences, and discussion sessions. We used them in the following combinations: Audio only, audio synchronized with the slides used by the speaker during the presentation, and audio plus the transcript of the address. Each of these has advantages and drawbacks, which must also be considered with reference to the labor required to prepare the Web presentation.

artNtec: Perspectives from WWW Users and Designers on Interface, Metaphor, and Content

Phoebe Jacobson
Univ. of Illinois at Urbana-Champaign
pjacobso@coe.uga.edu

artNtec is a pointer to architectural CAD resources on the Web. The goals of *artNtec* are twofold. First, it is designed to compare user preferences on four different interfaces (outline, text with hotlinks, icon, and graphic map) for WWW documents. artNtec uses four different menu choices to present the same contents. Secondly, artNtec is designed to utilize content sensitive metaphors (in this case, floor plan metaphor) to help elicit their functional mental models when navigating through different sections (using rooms metaphors such as gallery, library, learning center, studio, guest room, and market place).

artNtec was published on thc Web to a small amount of users. Architects visited *artNtec* tended to like the visual presentations (e.g., floor plan interface), even though it took more time to download the graphics. Non-architects, on the other hand, tended to prefer "outline" interface for efficiency reasons.

In addition to on-line survey, the author of *artNtec* also interviewed web users and designers in various skill levels to report on different perspectives of how on-line materials should be designed and utilized.

SAEBIT : Multimedia Authoring Tool for Educational Software

S.M. Jung (Korean Educational Development Institue, Seoul, Korea)
J.S. Song (Korean Educational Development Institue, Seoul, Korea)
S.T. Im (Div. Of I.C, Ajou University, Suwon, Korea, e-mail :stim@madang.ajou.ac.kr)
G.H. Jung (Div. Of E.E, Ajou University, Suwon, Korea, e-mail :khchung@madang.ajou.ac.kr)
J.T.Lee (Div. Of I.C, Ajou University, Suwon, Korea, e-mail :jtlee@madang.ajou.ac.kr)
K.H. Choi (Div. Of I.C, Ajou University, Suwon, Korea, e-mail :khchoi@madang.ajou.ac.kr)

The necessity and effectiveness of using multimedia in educational environment is increasing. According to the requirement, many multimedia authoring tools for CAI program have been developed. But since most of the tools are for professional programmers, the tools that can be used by instructors in classrooms who are not good at programming are needed definitely. To resolve this problem, we developed a multimedia educational software authoring tool, SAEBIT which helps instructors in classrooms to make educational programs easily. This paper presents a CAI program model, the structure and the functions of SAEBIT which have been distributed among about 10,000 schools in Korea since 1996 March.

Funded by the Canadian Cable Labs fund and Shaw Communications, this project examines learning models using electronic collaboration when age and gender are masked. Three geographically and economically diverse schools in Calgary are currently participating. A computer network links the three schools, The University of Calgary and Shaw Communications. Students range in age from 9 - 14 years. Identified to other participants by only a pseudonym, the students share scientific data within groups that span three schools.

Phase One was directed toward establishing the communications protocols and installing and learning the email, bulletin board and video-conferencing software that could enable students at different locations to collaborate on environmental science projects. Phase Two will start this fall, with students writing, editing and performing interactive cross site television broadcasts. The effects on learning will be observed in both phase one and phase two.

A Pan-European ATM-Based Teleteaching Experiment

U. Killat, J. Asmussen

Technical University of Hamburg-Harburg
Department of Digital Communication Systems
e-mail: {killat,asmussen}@tu-harburg.d400.de

M. Ajmone Marsan, M. Munafo

Politecnico di Torino
Electronics Department
e-mail: {ajmone,munafo}@polito.it

J. Quemada, J. Salvachua, T. Robles

Universidad Politécnica de Madrid
Dpto. De Ingeniería de Sistemas Telemáticos
e-mail: {quemada,jsalvachua,trobles}@dit.upm.es

A teleteaching experiment including four classrooms at different European universities is conducted over two semester periods. During Trial 1a course on "Teleteaching via ATM-networks" has been given which covered the networking prerequisites of the trial and the teleteaching application proper. The four lecturers used the CSCW tool ISABEL offering audio, video, viewgraph presentation, telepointing, teledrawing and session control. Feedback from the students has been obtained by evaluating questionnaires filled in after each lesson. Based on this input Trial 2 is prepared. In terms of equipment it differs from Trial 1 by introducing seperate audio/video streams which exploit ATM connectivity without using IP encapsulation. Greater network efficiency and better grade of service is expected. Further improvements are expected from precise guidelines for the preparation of courses and course materials. As the feedback of the students did not always unambiguously distinguish between drawbacks from the technological or the pedagogical aspects of the trial, an improved version of the questionnaire will be prepared.

The Canadian Visual Arts Information Network Student Interactive Imaging Program

William Kirby
Centre for Contemporary Canadian Art
Canada
w.kirby@ccca.ca

The Centre for Contemporary Canadian Art (CCCA) is developing the Canadian Visual Arts Information Network (CCCAnet) based on a database of information about contemporary Canadian artists, with digitized images of their work. To build the database the CCCA established the Student Interactive Imaging Program which engages high school students in the digitizing of images, interaction with practising artists, and the development of a web site. As a learning activity, both the development and the use of the Canadian Visual Arts Information Network is a rich, multi-faceted environment that promotes many effective learning principles. The CCCA's on-line database is based on the Multi MIMSY 2000 Information Management System developed by Willoughby Associates of Winnetka, Illinois. To add a further interactive component to CCCAnet, the CCCA is experimenting with JETS, a Java-enabled 'TeleCollaboration System' designed for the real-time sharing of Java applets software, which has been designed and developed at the Multimedia Communications Research Laboratory at the University of Ottawa.

The Role of the Computer Science Department in K-12 Education

Professor Roberta Klibaner, Department of Computer Science, College of Staten Island, CUNY, Staten Island, New York, U.S.A., Klibaner@postbox.csi.cuny.edu

Professor Marianne Carlin, Department of Computer Science, College of Staten Island, CUNY, Staten Island, New York, U.S.A., Carlin@postbox.csi.cuny.edu

Leaders in industry and state government are committed to equipping the schools in New York State with the technology needed to join the *National Information Infrastructure*. The Computer Science Department has taken on the role of helping teachers navigate the technology hurdle, encompassing exposure, evaluation, collaboration, integration and dissemination. Teachers are often overwhelmed by the hype that surrounds the selection and integration of the new technology. Computer Science faculty, who both understand the technology and are familiar with classroom teaching methodology can guide K-12 teachers through the decision making process. Formal courses and workshops have been utilized to aid in the integration of technology into instructional practices of public school educators. Curriculum specialists exposed the teachers to current software packages, which stressed a thematic approach to Social Studies and Language Arts. Other experts explored computer software for problem solving in mathematics and a hands-on discovery approach to learning science.

Multi-user, Interactive Concept Mapping Tools for the Learning Web

Rob Kremer and Roberto Flores-Mendez
Knowledge Science Institute, University of Calgary
Calgary, Alberta Canada T2N 1N4
kremer@cpsc.ucalgary.ca

The demonstration compliments two papers in these proceedings: Rob Kremer, "Multi-user Interactive Concept Maps for the Learning Web", and Roberto Flores-Mendez, "Java Concept Maps for the Learning Web." The demonstration will show several different concept mapping tools developed at the Knowledge Sciences Institute at the University of Calgary. The demonstration programs allow users to create, edit, and store graphical concept maps using a direct manipulation user interface. Users can easily re-arrange nodes in a map by using the mouse to "drag" nodes around the display surface. Arcs are attached to nodes by drawing or dragging their endpoints onto the nodes. Arc endpoints automatically move to follow the nodes they are attached to. These features combine with other direct manipulation features to provide a simple and intuitive interface for concept map editing.

The Engineering CALGroup.

Dr R M Lloyd. School of Engineering, Cardiff, University of Wales, UK. LloydR@cf.ac.uk

Engineering CALGroup is one of the Projects set up and funded under the Teaching and Learning Technology Program (TLTP) in 1992 to create Computer Aided Learning material for engineering undergraduates in a variety of disciplines. CALGroup have produced over 60 modules covering topics in electrical and electronic engineering, mechanical engineering, thermodynamics and fluid mechanics, design, manufacturing and mathematics.

Most of the material is aimed at first and second year students. Much of it is also suitable for foundation year students. It is anticipated that its main role will be to supplement lecturers and assist in achieving a consistent level of subject coverage across a class. It is also popular for revision purposes.

This demonstration will showcase the suite of CAL material produced by the Engineering CALGroup, a consortium of UK academic engineering departments funded under the TLTP programme. Delegates will be free to try out the CAL modules and information on the material and the CALGroup User Club will be available.

For additional information email: calgroup@cbltech.demon.co.uk

PAYING ATTENTION TO MULTIMEDIA: LEARNING FROM THE DUAL CHANNEL INTERFACE

Bruce L. Mann
Memorial University
bmann@calvin.stemnet.nf.ca

Evolving hardware and software attributes will surely permit users more adaptive and nonlinear interactions, and a higher capacity for differentiating audio and visual presentations. Moreover, researchers can't always find reliable information on how to focus human attention on competing tasks in contemporary interactive programs and online services. This paper introduces the SSF Model for assigning structural and functional attributes of audio into educational computer programs. The SSF Model is comprised of two operations: 1) assigning functions to the auditory events; and, 2) structuring the auditory events with co-existing visual objects. Although this model can be applied to any didactic or interactive learning environment with audio digitizing or synthesizing attributes, its application should be selective and fully integrated with current theory and exemplary practice. While the model may not be ideal for applying sound to visuals, recent findings in some educational settings suggest a better-than average probability of success.

Applying Education by Design in Distributed Hypermedia Environments

Lilia Matias Feijó e-mail: liliamf@usp.br
http://www.futuro.usp.br/~lilia
School of the Future, University of São Paulo, Brazil

Romero Tori e-mail: rometori@usp.br
http://www.pcs.usp.br
InterLab - Interactive Technology Laboratory
Polytechnic School - University of São Paulo, Brazil

Distributed hypermedia environments, which presuppose a distributed representation of knowledge, integrate hypermedia systems interactive features with computer networks. By combining these two systems which have proven their effectiveness for educational purposes [Barker, 1996], [Cohen, 1996] distributed environments may be an efficient way to encourage learner-centered education, aimed at a more effective learning process.

This work has been developed at University of São Paulo for our undergraduate courses. The primary objective is to provide a collaborative, experencial, active and multisensory learning. We have made use of learning by design [Shepard,1991], through which students may learn by developing enticing projects of their own interest. These are projects and subprojects jointly developed with or supported by instituitions within the community, in which students will put the concepts assimilated into practice. While working to shape ideas, students develop their different skills [Gardner, 1993] to overcome difficulties in making such ideas feasible, thus constructing knowledge.

Axiomatic and Ancillary Use of E-mail in Preservice Education Courses

Patricia A. McGee
Division of Education
The University of Texas at San Antonio
USA
pamcgee@tenet.edu

Wanda Hedrick
Division of Education
The University of Texas at San Antonio
USA
whedrick@texas.net

Drawn from their personal experiences, the authors describe how they each have used electronic-mail (e-mail) in different ways for different purposes.

Hedrick uses e-mail as an axiomatic tool in a field-based reading course. Students spend most of course time tutoring elementary students. E-mail is a vehicle for peer-to-peer conversing about problems, concerns and successes. Student -instructor e-mail is an invaluable and private consultation medium. E-mail is a critical and central tool in tying together field experiences and course learning.

McGee uses e-mail as ancillary tool in a field-based elementary teaching method's course. The class meets weekly and students spend 25 hours in local schools observing and teaching. Student send reflections via e-mail and then are given a variety of opportunities for other tasks. Although not a critical component of the course, students use the medium in a meaningful way and begin to value the function of e-mail as a tool.

Interactive User Configurable CAL . A Working Example in Epidemiology.

R.J.Moir

and J.D.Baty

Department of Molecular and Cellular Pathology
University of Dundee Medical School
Ninewells Hospital
Dundee
Scotland UK
r.j.moir@dundee.ac.uk
j.d.baty@dundee.ac.uk

C.Florey

Department of Epidemiology and Public Health
University of Dundee Medical School
Ninewells Hospital
Dundee
Scotland UK

c.florey@dundee.ac.uk

We have produced a teaching package for Epidemiology, for which a major design goal was the provision of a major degree of end user configurability. This allows the teacher to incorporate their own epidemiological data sets, additional subject modules, interactive question and answer sessions and external software links within the package. The structure and flexibility of our package is based on linking three distinct software components. The first is the user interface and the interactive exercise sections, which are written in Visual Basic. These exercise sections can be linked via DDE to a hypertext program, and from within both programs, links are established to conventional help files which act as a glossary. The programs menu bar also links to an MCQ program. While the package is a complete piece of courseware, the teacher can configure the presentation and content to suit a range of users and their own areas of interest and expertise.

The Internet - Communicating, Accessing & Providing Information: An On-line Web-based Course

T. Craig Montgomerie & Dwayne Harapnuik
Division of Technology in Education
University of Alberta
dwayne@oanet.com

Abstract: This paper discusses the development and delivery of an award winning credit course: *The Internet: Communicating, Accessing & Providing Information* (Montgomerie & Harapnuik, 1996) which is delivered completely over the Internet. Since May of 1996 over 200 students have completed this online course. The paper provides a description of this course as well as a set of observations and recommendations for the development of future courses. After a discussion of the development of the course, the philosophy of the course is presented. A discussion of the structure of the course includes the instructional design, an acknowledgment of andragogical principles and the support for multiple methods of learning as well as a discussion of the technical details of the course design. Finally, a set of observations, suggestions for improvements and recommendations for future course development are provided.

Using a Wearable Computer for Mobile Training and Performance Support

Lawrence J. Najjar
Multimedia in Manufacturing Education Laboratory
Georgia Tech Research Institute
GTRI/EOEML/MARC Room 335
Atlanta, GA 30332-0823 USA

gt4708d@prism.gatech.edu
http://mime1.marc.gatech.edu/EPSS

Jennifer J. Ockerman
Multimedia in Manufacturing Education Laboratory
jojo@chmsr.gatech.edu

J. Christopher Thompson
Multimedia in Manufacturing Education Laboratory
chris.thompson@gtri.gatech.edu

For training to be effective, it should be consistent with several challenging guidelines. These guidelines include:

- Give training when the learner needs it.
- Give training where (physically) the learner needs it.
- Train the learner on only the information that the learner needs.
- Allow the learner to control the training.
- Use the medium (e.g., text, audio, drawings, video) that most effectively communicates the information being learned.
- Emphasize performance rather than knowledge.
- Shorten the time between learning and application.

We combined a wearable computer and an electronic performance support system (EPSS) to give mobile users the training and task support they need, when they need it, where they need it, under the users' control. Our system also eliminates the gap between learning and applying skills. The computer includes a head-mounted display, earphone, microphone, wireless network, batteries, and voice-recognition software. The EPSS includes helpful multimedia information.

An ITS on the WWW with Interactive and Adaptive Courseware

Kiyoshi NAKABAYASHI, Mina MARUYAMA, Hirofumi TOUHEI,
Yasuhisa KATO, Kunihiro TAKIUCHI, and Yoshimi FUKUHARA
NTT Information and Communication Systems Laboratories
Tokyo, Japan
E-Mail: naka@isl.ntt.co.jp

We have developed an intelligent tutoring system(ITS) on the WWW called CALAT which is presented in ICCE95 and WebNet96. The system consists of an WWW server on which ITS process runs for each individual student.

The current implementation supports the individual adaptation capability with which appropriate courseware pages are presented by analyzing the user's answers to the exercises, progress speed, and other characteristics. Interactive simulation has also been implemented in which target(simulated) environment is defined as a state transition machine executed on the server.

In this demonstration, following new features of CALAT will be exhibited:

- an adaptive HTML-based courseware utilizing existing HTML documents as an ITS material.
- an interactive simulation environment implemented with simulation engine written in Java applet running on the client.

These features are intended to utilize the standard data format, protocols, and software platform, so that the courseware design flexibility can be maximized.

ADAPTING MULTIMEDIA TO THE WEB FOR USE IN INTERNET-DELIVERED COURSES

Peggy O'Neill-Jones
Department Chair, Technical Communications
oneilljp@mscd.edu

Clark Germann
Associate Professor, Technical Communications
germannc@mscd.edu

Metropolitan State College of Denver
Technical Communications Department
Campus Box 35, PO Box 173362
Denver CO USA80217-3362

Over the years, problems inherent to the quality of distance courses have become well known--lack of interactivity, lack of collaboration, and lack of interpersonal communication to name a few. Although the Internet delivery method has helped resolve some of these issues, much work remains to be done. Stated another way, Sherry (1995) writes that the following components need to be present in any successful distance course: interactivity; active learning, visual imagery, and effective communication. This poster session will demonstrate how Asymetrix Toolbook II and other similar software can be used to produce interactive multimedia files that can be accessed by students on the World Wide Web. Asymetrix Toolbook II is one new software product used to deliver sophisticated multimedia content on the Internet in several different ways: the traditional file downloading, using a browser plug-in called Neuron, hybrid HTML and CD ROM, hybrid HTML, Neuron and "smart streaming", and HTML/JAVA conversion from a Toolbook file. The well known technique of placing a file on your server and having your user download the file is an option. The disadvantages are the time required to download and that Toolbook is Windows-only software.

State University of New York Empire State College's The Writer's Complex

Center for Learning and Technology
lgreenbe@sescva.esc.edu

at
State University of New York, Empire State College, USA

Planned Demonstration:

We plan to demonstrate SUNY Empire State College's online writing center, The Writer's Complex. Participants will have the chance to work through its many rooms and comment on their experiences with this lab as well as other OWLS with which they are familiar. Participants can get a sense of the structure and underlying philosophy that went into the creation of the Complex. We hope to encourage additional, creative ideas for the use of this particular student-centered lab, and we hope to engage in a broader discussion about the use of an online writing lab as a structure for teaching and learning. We also hope, through our conversations, to foster collaboration among institutions through the vehicle of this online writing lab.

Edith Cowan University
a.omari@cowan.edu.au

The purpose of this Poster Session will be to display an Internet activity within our local elementary school that has grown from a trial one year ago to an important part of the school curriculum. The activity involves travelling buddies, toy animals shared between classes around the world. The project started as part of a larger Travelling Buddy project organised and coordinated from Chisholm Primary School in the Australian Capital Territory. One class in our school hosted a buddy from Chisholm and created a buddy of its own, Frillbert, for the children at Chisholm. The children enjoyed sharing experiences with the toys through writing and e-mail and this provided an impetus for other teachers in the school to join in. As well as Frillbert, there is now Puddles the platypus from Year 2, Ozzie Roo from Year 2 and Connie Cockatoo from Year 3. The Booragoon buddies have now travelled to several schools and by mid 1997 should have been around the world and back several times.

The development of the Multimedia CAL System for Education in Japanese on the WWW

Kenji Omae, ChunChen Lin, Seinosuke Narita
Department of Electrical, Electronics and Computer Engineering,
School of Science and Engineering
Waseda University, Japan
E-Mail: {omae,lin,narita}@narita.elec.waseda.ac.jp

It is of great significance for Japanese learners to have not only classroom lectures but also sufficient time to study by themselves. We have been developing an effective multimedia CAL system for learning Japanese on the WWW. Most works developed so far for learning Japanese on the WWW seem not practical because they are mainly composed only of texts. On the contrary, the proposed system incorporates voice sounds of native speakers and animations of Japanese writing to help learners study effectively and efficiently.

The demonstration will show an effective system for Japanese education on the WWW.

IMPLEMENTATION OF A DISTANCE EDUCATION PROGRAM LEADING TO A BACCALAUREATE DEGREE IN VOCATIONAL EDUCATION

Dr. Betsy Orr
Dr. Cecelia Thompson
Dr. Dale E. Thompson
Department of Vocational and Adult Education
The University of Arkansas

and

Robert W. Craig
Department of Educational Technology
The University of Arkansas

Distance learning is achieved by linking teachers and learners in different locations by use of technology. Cartwright (1994) believed that the three crucial components of distance learning are interactivity, multiple locations and synchronous or asynchronous time frames.

One of the present distance education programs at the University of Arkansas, Fayetteville, offers teacher education classes for community college technology instructors. The distance education program is based on the Fayetteville campus of the University of Arkansas and connected to six university and college campuses. The goals of the distance education program are to help participants develop improved teaching skills and achieve a baccalaureate degree in vocational education. The participants are full-time instructors at twelve community and technical colleges located throughout Arkansas. All participants enrolled in the distance education program have worked in industry but have not completed college degrees or taken educational courses.

Information Technology: Subject and Tool in Mathematics and Science Preservice Courses

Leslee Francis Pelton, Kathie Black
Department of Social and Natural Sciences
Faculty of Education
University of Victoria
Canada
lfrancis@uvic.ca, kblack@uvic.ca

This session highlights projects using telecommunications in preservice teacher education as a tool for learning rather than the subject to be learned.

Learners in science methodology classes were introduced to instructional technology through instructional modeling of databases, microcomputer-based laboratories, word processing, computer graphics, desktop publishing, hypermedia, and Internet as well as multi-media presentations. Further attention was given to directing students in the classroom application of these tools in a variety of content applications for the science classroom.

Telecommunications was used to manage three different preservice courses - a technology course, a mathematics content course, and a mathematics methods course. Courses had a World Wide Web home page containing a course syllabus, readings, assignments, and links to useful Internet resources. Students communicated with each other electronically using either a news group or e-mail. Assignments which could be submitted electronically were sent as e-mail attachments.

Studios for Inter-Institutional Collaborative Engineering Design

Bala Ram (ram@ncat.edu)
Shih-Liang Wang (slwang@ncat.edu)
Eui Park (park@ncat.edu)
Jin Jeong (jeong@ncat.edu)

College of Engineering
North Carolina A&T State University
Greensboro, NC 27411

The Realization Consortium is made up of five universities, Cornell University, Massachusetts Institute of Technology(MIT), North Carolina Agricultural and Technical State University(NCAT), Tuskegee University, and Worcester Polytechnic Institute(WPI) along with the Society for Manufacturing Engineers(SME). The goal of the consortium is to initiate a systematic reform of undergraduate engineering education by providing an opportunity for engineering students at all levels to design and manufacture products to meet customer needs (i.e., participate in the product realization process). To achieve this goal, the five universities have set up Design Studios.

The Design Studio at each of the five universities is interconnected for visual and audio communication, as well as the sharing of design data. All six Design Studios have some common hardware and software. However, each institution has developed a different configuration that meets its campus' needs. The Design Studios have been used broadly in two ways. At each institution, the studios have facilitated team projects and industry-sponsored projects with significant industry interaction. In addition, the studios have also been used by two multi-campus teams, to complete significant design and prototype development projects.

Acknowledgements: This work has been partially supported by the multi-agency Technology Reinvestment Program as National Science Foundation grant number DMI-9413089

Argumentation and Hypermedia

Curriculum Unit for Undergraduates

April T. Reed
Doctoral Student
Dept. of Communication Studies
West Virginia University
USA
aprilreed@aol.com
areed@wvu.edu

Descriptive Overview :

This unit is designed for undergraduate students, and centers on the following aspects of public speaking: 1) topic creation and formation; 2) developing arguments for persuasion; 3) recognizing and analyzing arguments; and 4) organization. This instructional unit uses a database of propaganda analysis called *Powers of Persuasion*, and the program *Written Argumentation*, a tutorial on argument models.

This unit can be used either as a one-credit undergraduate course on argumentation, or as one segment of a three-credit course on presentational speaking.

Since most students do not find this subject intriguing enough for intrinsic motivation, other instructional methods to increase extrinsic motivation need to be applied. For these reasons, this curriculum unit incorporates hypermedia through including both instructor-based and student-based computer programs. The instructor-based program was chosen to allow students to experience a wide variety of "real-world" argumentation examples. The student-based program was chosen to allow students the opportunity to create and refine their arguments.

Using Technology to Practice Social and Emotional Intelligence

J. Theodore Repa, Chair
Department of Administration, Leadership, and Technology
239 Greene Street, Suite 307
New York University-School of Education
New York, NY 10003-6674
212-998-5511 212-995-4041 (fax)

The Cave Project is a multi-media, computer simulation targeted towards pre-adolescents that focuses on enhancing their social and emotional intelligence. Defined as the ability to understand and manage social relations as well as mastery of the self, social and emotional intelligence has been shown to predict success better than IQ. The social simulation that will be demonstrated, projected to be delivered via the Web and CD-ROM technologies, has the players in a MUD environment enter a three dimensional cave with four artificially intelligent, pre-adolescent avatars using NYU's Improv and FacePad technologies. They get trapped and attempt to escape the various rooms of the cave where they encounter emotionally intelligent challenges associated with self-awareness, managing emotions, motivating oneself, recognizing emotions in others, and handling relationships. How well the players navigate these challenges, as decided by a panel of psychologists with expertise in social and emotional intelligence, determines how fast the players escape the cave.

Jump-Starting Web-Based Courseware Development

A. Rosselet
Computing, University of Toronto at Scarborough, Canada
rosselet@scar.utoronto.ca

The lessons gleaned from promoting the development of courseware web pages over the last 18 months are that to make rapid progress, a well-organised support system is required, driven by staff and early adopter faculty with hypermedia expertise, with student assistants available to carry out large parts of the implementation for non-technical faculty. computer and specialised media-handling equipment, and a variety of training and information sessions for faculty including a convincing argument for moving courses onto the Web. As well, to take full advantage of Web technology, classroom, network, dialup and public computing infrastructure should be in place on your campus.

Web courseware development can be effectively stimulated through funding competitions that accomplish several results: a) a sense of urgency to act is created by the temporary availability of funding and project support staff, b) faculty and staff brainstorm potential projects to prepare funding submissions, c) once projects are funded and underway and as the number of participants grows, a feeling of momentum develops that attracts the attention of other faculty who want to get on board, d) even those faculty who are not immediately funded are prodded into action when they see concrete evidence that courseware is not necessarily expensive or time consuming to produce. They then attempt to find creative ways to produce pages without central funding - for example through senior student projects in their courses. In our experience, the stimulus of central funding produces results far in excess of what one would predict.

Medicine and Multimedia: New Horizons for Target Population

Neide Santos*

ICE - Dept of Computer Science
Juiz de Fora - MG - Brazil

(neide,fernanda)@cos.ufrj.br

New technologies have not been intensively used to communicate with target people, mainly in the medical field. Updated health information for target population is an interesting area to join self-learning approach with user-friendly computing systems. High pressure is a common disease in 20% of the Brazilian population. So, we are developing an interactive multimedia to explain the main care with the health and it tries to answer the most usual questions about High Pressure. To reach the goal, we joined a multidisciplinary team: medical doctors; computing and education specialists and computer science specialists.

Our work aims to test new technologies efficiency as a communication channel to inform target population and to display information and orientation in kiosks at Brazilian public hospitals.

The prototype is now being tested with patients to improve interface and to make sure that the information displayed in the kiosk kits the medical goals.

Design of a Web-based Course on Comparative Advertising

John R. Savery, Ph.D.
Academic Technology Development
DePaul University, Chicago, U.S.A.
jsavery@condor.depaul.edu

Introduction:

A series of book chapters developed by Gordon Hutchinson, who works in the Japanese advertising industry and DePaul faculty member Dr. Denise Nitterhouse examined the sociological, philosophical, religious and cultural differences that influence the design of advertising in Japan and the United States. An understanding of these differences would provide both clients and advertisers with a basis for creating and evaluating advertising campaigns for the respective cultures. Thus, Japanese companies wishing to advertise their products in the US would benefit from a better understanding of their potential American customers, and American companies would benefit from a better understanding of their potential Japanese customers.

Incorporating rich, detailed examples and non-examples of print and video advertisements from each culture was seen as an essential element in developing an understanding of the similarities and differences between these two cultures in the field of advertising. Thus, a collaborative effort by the principle authors and team members in the Academic Technology Development group, produced a prototype of an instructional environment for the comparison of Japanese and American print and television ads. The use of the Internet to deliver this combined text and image instruction was a key component of the design.

Web-based Quiz Using Cookies

by Barry Shell and Gordon Ross
Centre For Systems Science, Simon Fraser University, Burnaby, BC, Canada
shell@cs.sfu.ca

A multiple choice quiz was designed for delivery over the web and tested in a one day online contest. The quiz uses Netscape cookie technology to track users scores during a session even if they leave the site and return hours later. The system is unique as it allows casual use of the quiz by anyone on the web. Only those who register are tracked. The system is a simple model for online course delivery that allows auditing. Problems are discussed and solutions proposed for dealing with students participating in secondary school computer labs behind proxy servers. Perl scripts for tracking and displaying user scores in a database were developed. Other scripts track individual player's answers in separate user files. We show how these files can be used to grade users, to analyse quiz response and usage and to foil potential cheaters. Cross-platform issues, program structure and perl programming ideas are discussed in the context of the World Wide Web delivery medium used. The function and structure of the quiz system can be demonstrated online from any Internet-ready computer by visiting www.science.ca/quiz.

Internet Technologies:
A Nation-Wide Extracurricular Program for K12 Students

Peter Soreanu [1]
The Open University of Israel, P.O.B. 309, 31033 Haifa, Israel
E-Mail: speter@actcom.co.il

Our aim was to test the feasibility of teaching Internet Technologies to K12 students from 4 schools around the country. Part of the work was done in the classroom, incorporated in the formal computer literacy teaching. We present the extracurricular part of the program.

The students' projects were related to various subjects like: video and audio on the net, Internet telephony, MOO programming, chat room building, 3D Worlds, VRML-based 3D structures, net viruses, connected devices, Java scripts etc.

We used a two-track tutoring approach: technical-consulting and administrative-monitoring. When needed, collaborative work was facilitated. We heavily encouraged the use of existing Internet-based resources, organized on-line events and taught them to make a technical presentation in electronic form.

We found that teaching Internet Technology at K7-K12 level is feasible and worthwhile and we recommend to implement this attractive and relatively cheap topic in technology education.

Interactive Multimedia Applications In Second Language Learning

Dr. Juan M. Sosa
Department of Linguistics
Simon Fraser University
Canada
sosa@sfu.ca

Leslie C. Paas
Department of Communications
Simon Fraser University
Canada
leslie@cps.ufsc.br

Luciane Reiter Frolich
Department of Foreign Languages and Literature
Universidade Federal de Santa Catarina
Brazil
reiter@ccc.ufsc.br

This project combines the design of a course interface/demo with the conceptualization of a methodology for second language leraning on the World Wide Web. The intent is to use networked multimedia to better approximate an immersion situation via interaction with native speakers and access to electronic publications and environments produced in the second language. The model also facilitates individual learning and communication between teachers and students. Exemplary second language learning exercises currently available online were compiled for the course demo, to form a self-learning component of listening, phonetics, reading, writing and game play. Communication tools include access to e-mail, and computer text and viedo conferencing. Further resources provided are on online dictionary, a databank of student grades and assignments, and course information.

USING A MICROWORLD TO MOTIVATE AND ENGAGE ADULT LEARNERS

Ms Sue Stoney, (author is a full-time student)

Pearson Street
Churchlands Western Australia 6018
phone: 619 272 8502
email: s.stoney@cowan.edu.au

Mr Brian Ducie,
Faculty of Business
Edith Cowan University
Churchlands, Western Australia, 6018
email: b.ducie@cowan.edu.au

INTRODUCTION

This poster aims to demonstrate a program written specifically to appeal to adult learners in a content area that is normally dry and unengaging. The area selected was a module on share valuation and investment. Traditionally this module is taught in a didactic fashion via lecture and seminar with heavy reference to the textbook. It was important to identify a means by which the information could be taught both to students on-campus as well as off-campus in remote locations. The major problem was how to incorporate the theory with practical understanding and application. The students also needed to see the impact which random events have on shares and gain feedback on their own share trading.

The microworld has been developed to accommodates eight motivational attributes of immersion; reflection; flow; collaboration; learner control; curiosity; fantasy and challenge. The microworld was designed to simulate a real investment house.

THE RELATIONSHIP BETWEEN STUDENT LEARNING PROFILE AND NAVIGATIONAL STRATEGIES IN A HYPERMEDIA ENVIRONMENT

Noelle D. Sweany
Dept. of Educational Psychology
The University of Texas at Austin
sweany@mail.utexas.edu

Doug C. Williams
Dept. of Instructional Technology
The University of Texas at Austin
dcw@mail.utexas.edu

While hypermedia is quickly becoming a powerful instructional tool, research is needed to determine how individuals progress through the environment and make sense of the incoming information. This exploratory study examines whether differences in navigation exist among students of varying motivational and self-regulatory levels. Students in an undergraduate English course at the University of Texas read through a Web-based hypermedia program that focuses on the women writers of the Romantic period. The students completed the Motivated Strategies for Learning Questionnaire (MSLQ). In addition, the navigational trails of the students through the hypermedia program were recorded. Specifically, scores on the Cognitive Strategies sub-scales of the MSLQ (Rehearsal, Elaboration, and Organizational) were compared with the students' navigational paths to examine if any patterns emerge among students of varying self-regulatory levels. Building on the work of Pintrich and Garcia, student profiles on all Motivational, Cognitive, and Self-regulatory components of the MSLQ were generated and compared with the subsequent navigational paths.

A Learning Environment to Support C Shell Programming based on Multi-Agent

Ryo Takaoka
The Graduate School of Information Systems,
the University of Electro-Communications, Japan
ryo@ai.is.uec.ac.jp

Toshio Okamoto
The Graduate School of Information Systems,
the University of Electro-Communications, Japan
okamoto@ai.is.uec.ac.jp

Recently, various systems based on agent model architecture have been developed. In these systems, 'agents' with their own goals and functions are embedded, and perform their own tasks through collaborating among them to achieve a goal as the system requires. Using this agent model for the construction of educational systems, adaptive configuration of the system is achieved. The purpose of this study is to propose a methodology to design an educational system based on agent model architecture. In this poster, we explain the organization of agents to be executed as an educational system, and how to recognize the role of other agents necessary to interact with these agents in the educational system. As a case to show the organization of agents, we display the configuration of an intelligent learning environment to support C shell programming in UNIX. Moreover, we explain the collaborative behavior of embedded agents in this learning environment.

Considerations for the Development and Use of Educational Software

E-mail: marciabc@music.pucrs.br

Educational software should be inserted into a pedagogical project with well-defined guiding principles. Its utilisation should target the creation of an educational environment favourable to the construction of knowledge, allowing the access to information and the communicative interaction among the participants in the process. To achieve such goal, the cognitive development of the user and the factors capable of influencing the development ought to be studied.

Due to the emerging necessities of a world which gets wider, and under constant changes, the educational software must forecast into their interfaces, features that allow the access to information, distribution of the resources available in computer networks, interactive and reflexive communication, aiming the sharing of ideas and problems that the new generations have to face. In sum, the educational software has a social role to play. Therefore, its construction should have in mind adequate theories to contribute significantly to the new society.

HATHAWAY PRIMARY SCHOOL: A MULTIMEDIA CASE STUDY

Rob Walker
Centre for Education and Change
Deakin University
AUSTRALIA
rob@deakin.edu.au

INTRODUCTION

'Hathaway' is a CDROM which provides extensive documentation relating to a primary school in Sydney's inner west. The school has a multicultural population (less than 10% of children speak English at home) in which the majority are Lebanese Moslems.

EDUCATIONAL USE

We have been using this material as the basis for an action research-based distance education course for teachers (around 200 each year). Our aim is to get teachers thinking about the complexity of schooling, the interactions between factors outside the school and inside the classroom and the nature of professional learning as reflection on action.

NATURE OF THE MATERIAL

The CDROM has been assembled using Supercard and contains more than 260 scanned images, 150 colour photographs, 30 minutes of full-motion video and two hours of audio linked to still images as well as many hundreds of pages of text. Currently it is available in Mac version only while we await the release of the Windows version of the software.

Innovative features include the linking of transcripts to video (especially important for NESB users but also enhancing the capacity of the material for use in research training) and the capability for students to assemble their own 'guided tours' through the material, incorporating links to particular pages, even to individual words. The material also has an extensive search/query function which provides students with navigational help.

The demonstration will consist of a thirty minute 'guided tour' through some of the most interesting pages as the basis for interation and discussion with the presenter, The tour will be repeated three or four times. Also available will be a handout giving important relevant information and access to a number of papers which provide accounts of research and evaluation studies related to the program.

Currently the CDROM is being used in our own courses and at a number of other universities in Australia, the UK, Austria, Norway and the US. Evaluation comments are being collected via the web site and access to this material will be available during the demonstration.

More detailed information can be found at the Hathaway web site:
http://www2.deakin.edu.au/sdg/hathaway/default.htm

Interactive WEB Language Learning

Fawn Whittaker, LLC Division, BYUH, USA, whittakf@byuh.edu

What is language if one cannot interact with it? At best, interaction takes place directly with others who natively use the target language. However, language students can also cognitively communicate via the Internet by three convenient means.

Netforms

Netforms enables students to select among multiple choice answers and to interactively receive immediate feedback as to the correctness of the grammatical, vocabulary, or translation answer they have selected.

Frame Manipulation

The student can interactively apply language skills by clicking on (Frame) A or (Frame) B depending upon which frame, according to the student's opinion, provides the correct translation or answer, again receiving immediate feedback.

Image Mapping

If a student wishes to know the written and audio form of pictorially-depicted language, the student can click on the aspect of a drawing or picture which is to reveal the desired linguistic information and again interactively receive immediate feedback.

Comparing Multimedia & Traditional Instruction of Preservice Teachers in Modeling Whole Number Algorithms

Brenda T. Wilson
West Virginia University, Morgantown, USA
& Glenville State College, Glenville, WV, USA
e-mail: bwilson@glenville.wvnet.edu

Kevin A. Koury
West Virginia University, Morgantown, USA
& West Chester University, West Chester, PA, USA
e-mail: kkoury@wcupa.edu

The National Council of Teachers of Mathematics recommends the use of physical materials to model procedures and link manipulation of these materials to the steps of arithmetic algorithms (NCTM, 1989). *Linking the Manipulation of Materials to the Modeling of Whole Number Algorithms* is a hypermedia program designed to help preservice teachers develop this skill. It contains multiple examples of modeling whole number algorithms with physical materials. Interactivity is encouraged through the use of menus and buttons for navigation, access to scope and sequence skills, and access to pertinent NCTM standards. It provides opportunities to describe the use of this skill in the classroom and to model algorithms by dragging manipulatives on the screen.

The purpose of this poster session is to demonstrate the software and present the results of a study comparing its effects to those of traditional instruction.

MULTIMEDIA INTERACTIVE LEARNING SYSTEM (MILS)

Jacqueline Tsang Wong and Philip Kwok
Department of Computing
The Hong Kong Polytechnic University
Hong Kong.
email: csjawong@comp.polyu.edu.hk

MILS is not a teaching aid, it is a complete teaching system. It will take the student from one definable skill level to another and it is able to give all the necessary guidance and feedback. The system is a multimedia interactive learning and authoring tool.

MILS consists of four main modules: Contents Authoring, Exercise Authoring, Contents presentation, and Exercise Presentation.

. The Contents of knowledge in the MILS are presented with help of multimedia technology - pictures, sound, videos and text in an interesting way to attract the students' concentration. Students can review the contents anytime and select whatever they want to learn.

The Exercises are presented one after one and in three types of format: Multiple Choice questions, Matching questions and True and False questions. An immediate feedback will be given to students after they answered the questions.

TECHNOLOGICAL REFORM IN RUSSIAN UNIVERSITIES:

Andrei Zhegin
Herzen State Pedagogical University of St. Petersburg, Russia
vys@rgpu.spb.su

Nancy G. Mims
State University of West Georgia
nmims@westga.edu

Recent political changes in Russia have lead to radical transformation in educational paradigms. The term educational technology, in spite of its urgency is not expressively defined, therefore it is the subject of wide discussion. These new paradigms affect three aspects of the educational process: content, structure of programs and technology. Reorganization of the first and second aspects made after rapid social changes of the late 1980's and early 1990's has stabilized, and the development of content and structure, although slow, is extensive. The development of the technological component in education is the subject for intensive research and projects at Federal and regional levels. Utilizing computers to work with data bases, global networks, multimedia, and other software gives students and professors more opportunities to analyze information and to work with more complex decisions and problem solving. These multi-processes are important in all aspects of Russia's educational changes, and the technological direction is rapidly becoming a priority.
